

Rare Opportunities: *Seeking New Physics with Rare Decays of Light Particles*

Douglas Bryman
University of British Columbia

“Rare Opportunities” Outline

Lecture I

- Introduction and Overview
- Motivation from theory for modern studies of rare μ , π , and K decays; access to new physics at high mass scales.
- Experiments and experimental techniques for high precision and high sensitivity measurements of rare and ultra-rare processes:

Muons: $\mu \rightarrow e\gamma$, Nuclear $\mu \rightarrow e$ conversion

Pions: $\pi^+ \rightarrow e^+\nu/\pi^+ \rightarrow \mu^+\nu$ Branching ratio

Lecture II

Kaons: $K^+ \rightarrow e^+\nu/K^+ \rightarrow \mu^+\nu$

$K^+ \rightarrow \pi^+\nu\bar{\nu}$

$K_L^0 \rightarrow \pi^0\nu\bar{\nu}$

Standard Model

Not likely the whole story

- *Cosmological issues*: inflation, dark matter, dark energy, **matter anti-matter asymmetry**
- *Theoretical issues*: gravity, neutrino mass, **flavor problem**, hierarchy problem,...

LHC: Direct exploration of the TeV energy scale.

Flavor Physics (e.g. Rare Decays):

Explore the symmetry properties of new degrees of freedom at high mass scales “1-1000 TeV”.

The Flavor Puzzle

Quarks		
u	c	t
d	s	b

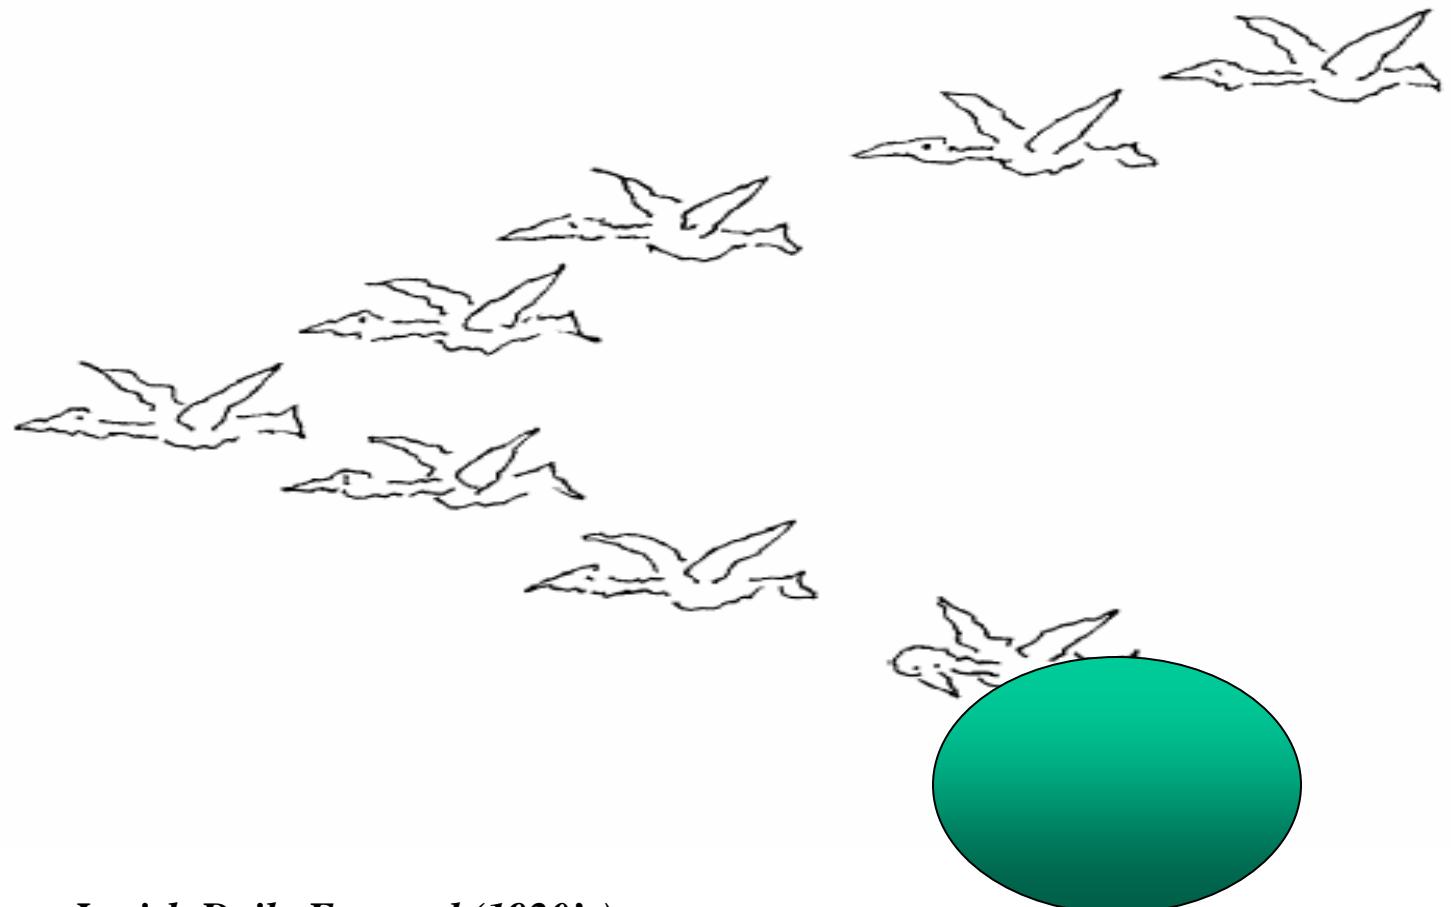

Leptons		
e	μ	τ
ν_e	ν_μ	ν_τ

- Weak states \Leftrightarrow mass states
- Quark, lepton flavors not conserved
- Three flavors \Rightarrow **CP violation**, BAU,...

Unexplained observations (no theory of flavor):

- Huge mass differences between and within the generations
- Universality of interactions
- Symmetry between lepton and quark sectors

Seeking Answers with Rare Decays

Cartoon from Jewish Daily Forward (1920's)

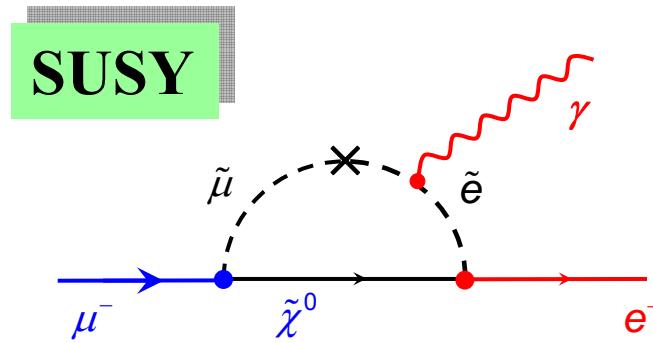

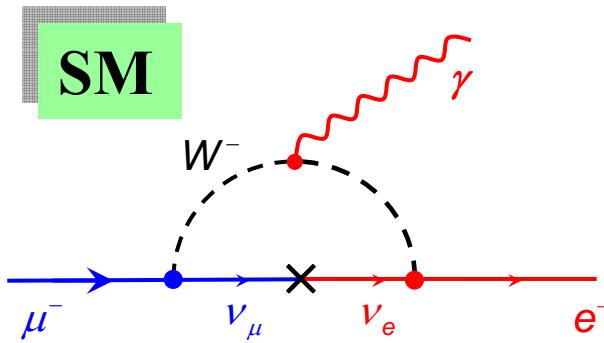

Overview of Light Particle Rare Decay Experiments

State of the art: single event sensitivity, 10^{-12}

Flavor Violation in the Charged Lepton Sector

$\mu \rightarrow e\gamma$

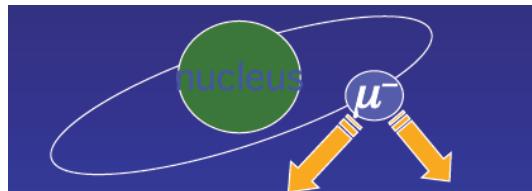

$$\text{BR}(\mu^- \rightarrow e^- \gamma) \Big|_{\text{SM}} \propto \frac{m_\nu^4}{m_W^4} \approx 10^{-60}$$

$$\text{BR}(\mu^- \rightarrow e^- \gamma) \Big|_{\text{SUSY}} \approx 10^{-5} \frac{\Delta m_{\tilde{e}\tilde{\mu}}^2}{\bar{m}_{\tilde{\ell}}^2} \left(\frac{100 \text{ GeV}}{m_{\text{SUSY}}} \right)^4 \tan^2 \beta \approx 10^{-12}$$

$\{\tan \beta \sim \text{ratio of } \langle H \rangle \text{ for 2 Higgs doublets}\}$

- Observation means new physics.
- Some SUSY models predict $\text{BR}(\mu \rightarrow e\gamma)$ near the experimental limit

$\mu^- \rightarrow e^-$ Conversion

Muon Capture

$$\mu^-(N, Z) \rightarrow \nu_\mu(N, Z - 1)$$

Decay in orbit

$$\mu^- \rightarrow e^- \nu \bar{\nu}$$

Or?

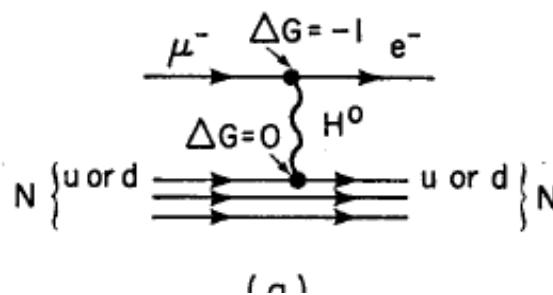

$\mu^- \rightarrow e^-$ Conversion

$$\mu^-(N, Z) \rightarrow e^-(N, Z)$$

Momentum $P_e = m_{\mu} - b.e. \sim 100 MeV/c$

Coherent, Neutrinoless

Sensitive to a wide variety of models at high mass scales:
Non-diagonal Z- μe , H- μe couplings, horizontal gauge bosons, heavy neutrino mixing, ...

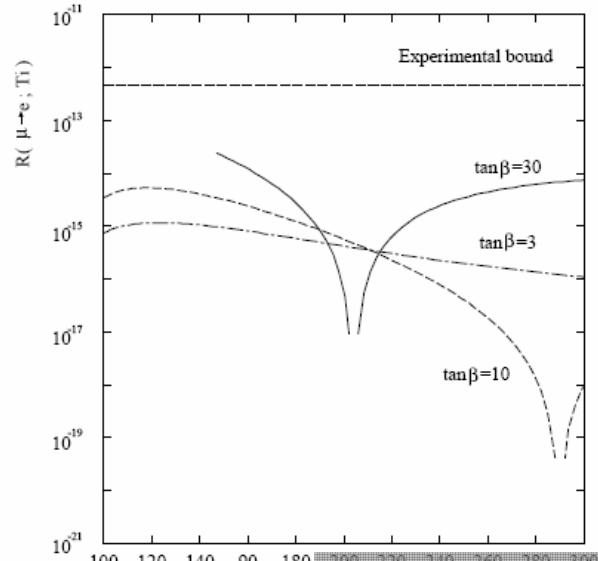

$$\frac{\Gamma(\mu^-(N, Z) \rightarrow e^-(N, Z))}{\Gamma(\mu^-(N, Z) \rightarrow \nu(N, Z - 1))} \sim \frac{1}{(M_H)^4}$$

Current limits $\rightarrow M_H > 340 TeV$

Updated from Cahn and Harari (1980).

Branching Ratios for $\mu \rightarrow e$ Conversion and $\mu \rightarrow e\gamma$ in a Minimal Supersymmetric Model (MSSM)

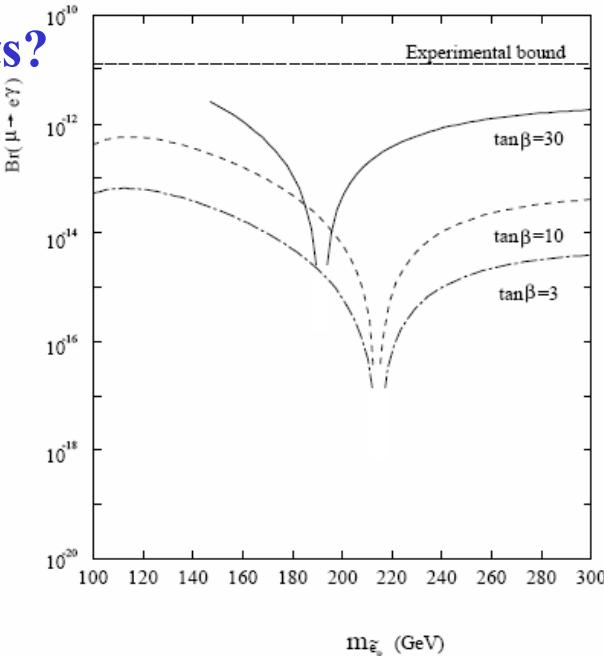

$R(\mu^- Ti \rightarrow e^- Ti)$

Slepton Mass (GeV)

$R(\mu \rightarrow e\gamma)$

Future expts?

$m_{\tilde{e}} \text{ (GeV)}$

Process	Current Limit	SUSY-GUT level
$\mu N \rightarrow e N$	10^{-13}	10^{-16}
$\mu \rightarrow e \gamma$	10^{-11}	10^{-14}
$\tau \rightarrow \mu \gamma$	10^{-6}	10^{-9}

$\{\tan\beta \sim \text{ratio of } \langle H \rangle \text{ for 2 Higgs doublets}\}$

J. Hisano et al., Phys. Lett. B391, 341 (1997).

V. Cirigliano, B. Grinstein, G. Isidori and M. B. Wise (2005);
Isidori FPCP (2006).

$\mu \rightarrow e\gamma / \mu - e$ Conversion vs. $\tau \rightarrow \mu\gamma$?

Example new physics theory: Lepton number violation, flavor violation decoupled;
Heavy rt-handed neutrinos. LFV in the charged sector related to neutrino mixing matrix.

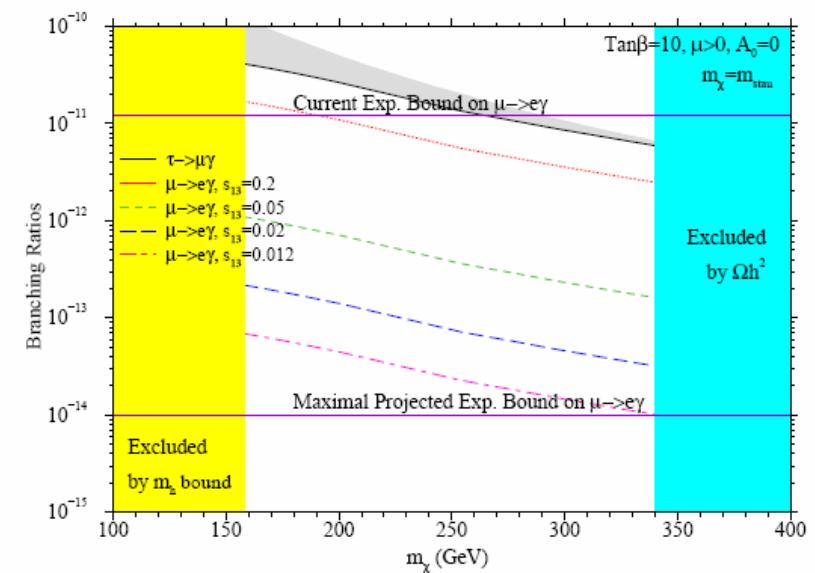

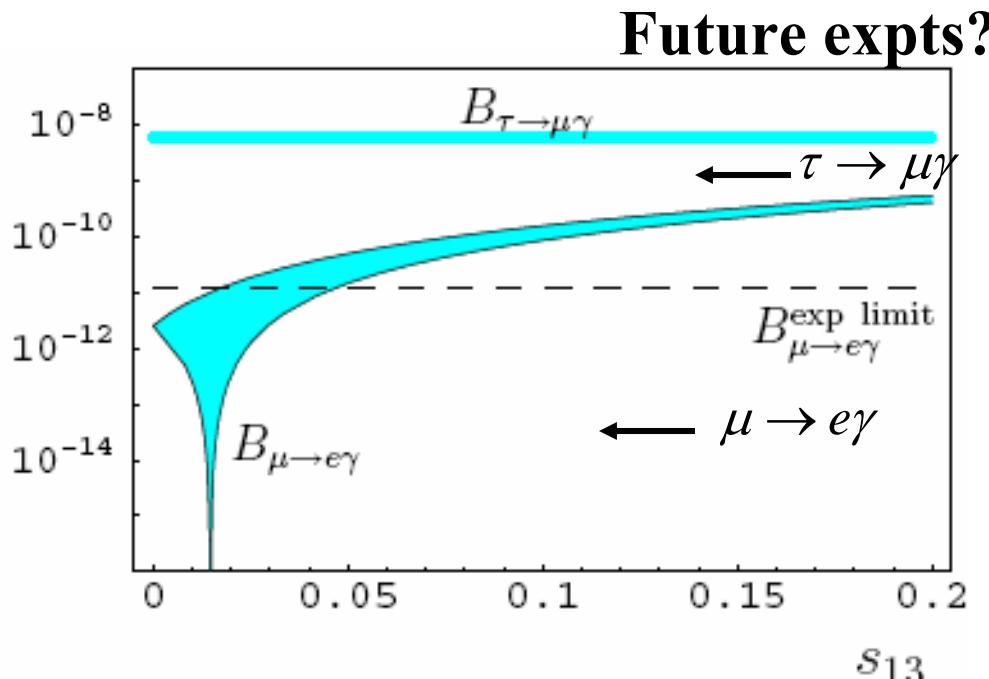

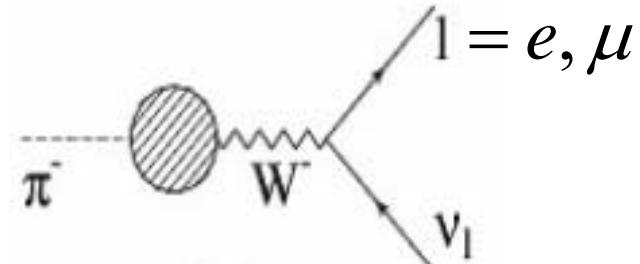

Figure 4: Isolevel curves for $\mathcal{B}(\mu \rightarrow e\gamma)$ and $\mathcal{B}(\tau \rightarrow \mu\gamma)$ in the MSSM (for $\tan \beta = 10$, $\mu > 0$ and $A_0 = 0$) compared with the present and future experimental resolution on $\mathcal{B}(\mu \rightarrow e\gamma)$ [35].

Limits on $\mu \rightarrow e\gamma$ & $\mu - e$ Conversion rule out observable
 $\tau \rightarrow \mu\gamma$ in many theories.

Important Element of the SM Story*

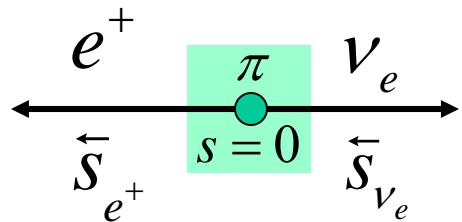

SM $V-A$ Hamiltonian: $(\pi/K) \rightarrow l\nu_l$

$$H = \left(\frac{g^2 V_{ud}}{8m_W^2} \right) \bar{l} \gamma_\lambda (1 - \gamma_5) \bar{\nu}_l \bar{u} \gamma^\lambda (1 - \gamma_5) d$$

$$= \left(\frac{g^2 V_{ud}}{8m_W^2} \right) \bar{l} \gamma_\lambda (1 - \gamma_5) \bar{\nu}_l \bar{u} \gamma^\lambda \gamma_5 d$$

Helicity suppression

Decay Rate: $\pi(K) \rightarrow l\nu_l$

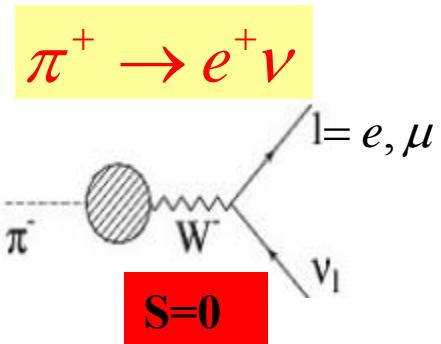

$$\Gamma(\pi \rightarrow l\nu_l) = \left(\frac{g^2 V_{ud}}{8m_W^2} \right)^2 \frac{m_\pi}{4\pi} f_\pi^2 m_l^2 \left(1 - \frac{m_l^2}{m_\pi^2} \right)^2$$

f_π defined via: $\langle 0 | \bar{d} \gamma_\lambda \gamma_5 u | \pi^+(p) \rangle = i f_\pi p_\lambda$

$e - \mu - \tau$ Lepton Universality

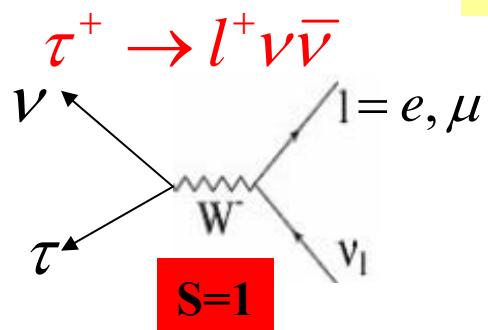

Standard Model: e, μ, τ have identical electroweak gauge interactions.

Differ only in mass and coupling to Higgs boson.

$$R_{e/\mu}^0 \equiv \frac{\Gamma(\pi^+ \rightarrow e^+ \nu)}{\Gamma(\pi^+ \rightarrow \mu^+ \nu)} = \frac{m_e^2}{m_\mu^2} \frac{\left(1 - \frac{m_e^2}{m_\pi^2}\right)}{\left(1 - \frac{m_\mu^2}{m_\pi^2}\right)} = 1.284 \times 10^{-4}$$

Independent of f_π, V_{ud} .

$$R_{e/\mu}^\tau = \left(1 - \frac{8m_\mu^2}{m_\tau^2} \dots\right) = 1.0282$$

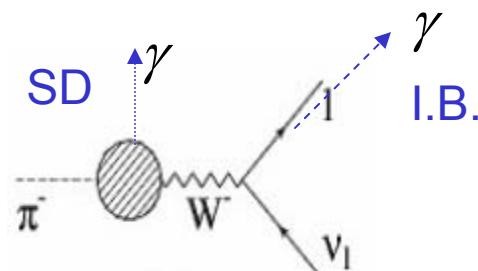

Unless... new physics does not respect universality.

Universality Tests

Mode	g_e/g_μ
$\pi \rightarrow e\nu/\pi \rightarrow \mu\nu$	0.9985 ± 0.0016
$K \rightarrow e\nu/K \rightarrow \mu\nu$	1.012 ± 0.010
$\tau \rightarrow e\nu\nu/\tau \rightarrow \mu\nu\nu$	0.9999 ± 0.0021
$\nu e/\nu \mu$ scattering	1.10 ± 0.05
W decays	0.999 ± 0.011

$$\pi^+ \rightarrow e^+ \nu$$

Radiative Corrections; Inner Bremsstrahlung; and Structure-Dependent Radiation:

$$\begin{aligned} \Gamma(\pi \rightarrow l \bar{\nu}_l (\gamma)) = & \frac{G_\mu^2 |V_{ud}|^2}{8\pi} f_\pi^2 m_\pi m_l^2 \left(1 - \frac{m_l^2}{m_\pi^2}\right)^2 \left[1 + \frac{2\alpha}{\pi} \ln \left(\frac{m_Z}{m_\rho}\right)\right]_\gamma \\ & \times \left[1 - \frac{\alpha}{\pi} \left\{ \frac{3}{2} \ln \left(\frac{m_\rho}{m_\pi}\right) + C_1 + C_2 \frac{m_l^2}{m_\rho^2} \ln \frac{m_\rho^2}{m_l^2} + C_3 \frac{m_l^2}{m_\rho^2} + \dots \right\}\right] \left[1 + \frac{\alpha}{\pi} F(x)\right] \end{aligned}$$

$[-4\% \text{ for } l=e]$
 $\left[+ \pi \text{ Structure-dependent } \pi^+ \rightarrow e^+ \nu \gamma \text{ terms} \right]$

where $G_\mu = 1.16637(1) \times 10^{-5} \text{ GeV}^{-2}$, $V_{ud} = 0.9738$

But, most factors
cancel in the ratio

$$R_{e/\mu}^{th} = \frac{\Gamma(\pi \rightarrow e\nu + \pi \rightarrow e\nu\gamma)}{\Gamma(\pi \rightarrow \mu\nu + \pi \rightarrow \mu\nu\gamma)}$$

$$R_{e/\mu}^{th} = R_{e/\mu}^0 \left\{ 1 + \frac{\alpha}{\pi} \left[F\left(\frac{m_e}{m_\pi}\right) - F\left(\frac{m_\mu}{m_\pi}\right) + C_2 \frac{m_\mu^2}{m_\rho^2} \ln \frac{m_\rho^2}{m_\mu^2} + C_3 \frac{m_\mu^2}{m_\rho^2} \right] (+SD_\pi) \right\} 8 \times 10^{-8}$$

F : kinematic factors

$C_2 = 3.1$ (Terent'ev)

C_3 : Small but
Model dependent
Marciano : 0 ± 10

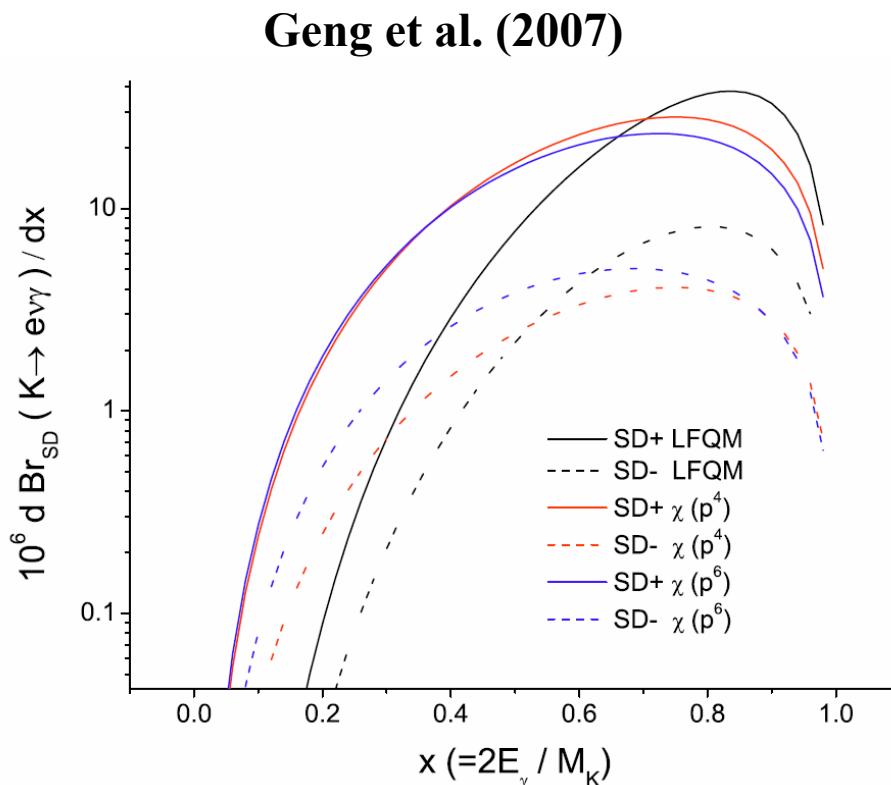

Pure Structure Dependent (SD) $\pi \rightarrow e\nu\gamma$
corrections are not helicity suppressed
but are small and known for π decay:

Structure Dependent Radiation in $K \rightarrow e \nu \gamma$ Decay

SD radiation: Not Helicity Suppressed; Large effect for $K \rightarrow e \nu$

$$\Gamma(K \rightarrow e \nu \gamma_{SD}) \sim \Gamma(K \rightarrow e \nu + K \rightarrow e \nu \gamma_{IB})$$

Calculated in Chiral Perturbation Theory CHPT $O(p^4)$ (Bijnens, Ecker, Gasser, 1992) and CHPT $O(p^6)$ and Light Front Quark Model(Geng et al. 2007, 1998*)

Form Factors

$SD^+ : V + A$

$SD^- : V - A$

Interference

Rates	$SD^+(x10^{-5})$	$SD^-(x10^{-6})$
CHPT $O(p^4)$	1.5	1.9
CHPT $O(p^6)$	1.4	1.1
LFQM	1.6	2.9
<i>Experiment</i>	1.52 ± 0.23	< 1600

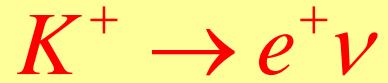

$$R_{e/\mu}^{th} = (1.2353 \pm 0.0004) \times 10^{-4}$$

(Marciano 2005) $\rightarrow \pm 0.0001?$

The most accurately calculated decay process involving hadrons (*and “could be better” W. M.*).

$$R_{K \rightarrow e/\mu}^{th} = (2.472 \pm 0.001^*) \times 10^{-5}$$

Finkemeier(1995)

Helicity suppression $5 \times \pi^+ \rightarrow e^+ \nu$

*Optimistic?

Structure dependent radiation not included.

Experiments

$\pi \rightarrow e\nu$

$$R_{e/\mu}^{\exp\pi} (\pm 0.4\%)$$

$$1.2265(34)(44) \times 10^{-4} \text{ TRIUMF (1992)}$$

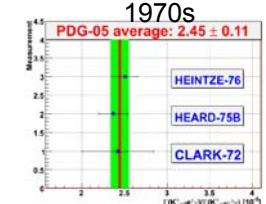

$$1.2346(35)(36) \times 10^{-4} \text{ PSI (1993)}$$

$K \rightarrow e\nu / K \rightarrow \mu\nu$

$$R_{e/\mu}^{\exp K} (\pm 2\%)$$

$$2.45(11) \times 10^{-5}$$

$$2.416(43)(24) \times 10^{-5} \text{ CERN(2006)}$$

$$R_{e/\mu}^{th} - R_{e/\mu}^{\exp} = 43(37) \times 10^{-8}$$

$$R_{e/\mu}^{th} - R_{e/\mu}^{\exp} = 56(46) \times 10^{-8}$$

Two new $\pi \rightarrow e\nu$ experiments.

Goals: $\pm(5) \times 10^{-8}$ (0.05%)

KLOE: Stay tuned next week ($\pm 1-2\%$?)

New $K \rightarrow e\nu$ experiment.

Goal: $\pm(10) \times 10^{-8}$ (0.3%).

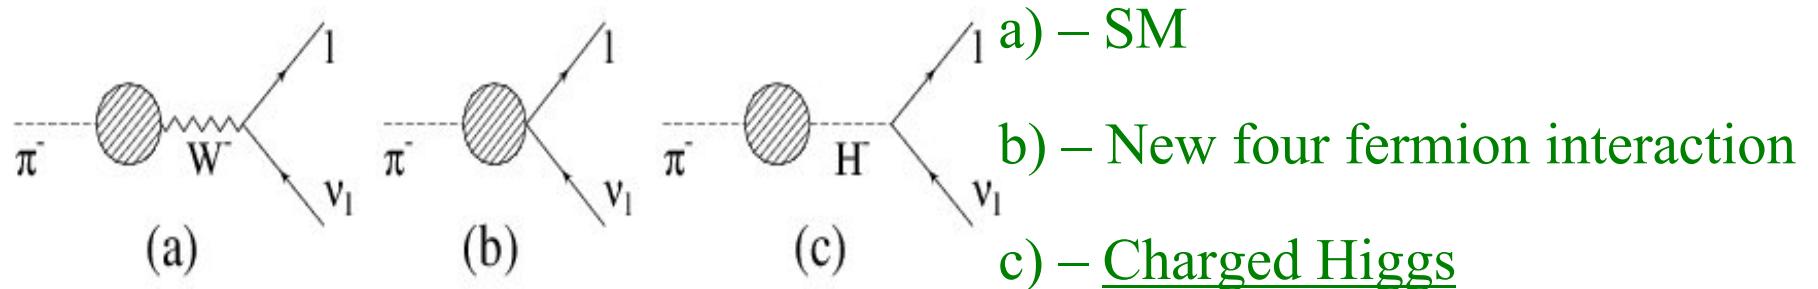

$$\pi^+ \rightarrow e^+ \nu$$

Beyond the Standard Model

High Sensitivity to New **Pseudoscalar** Interactions
which are not helicity suppressed.

PS contribution comes as interference with the axial-vector (dominant) interaction.

Effect is proportional to $1/\Lambda^2$ where Λ is the mass of the hypothetical particle.

$$1 - \frac{R_{e/\mu}^{New}}{R_{e/\mu}^{SM}} \sim \mp \frac{\sqrt{2}\pi}{G_\mu} \frac{1}{\Lambda_{eP}^2} \frac{m_\pi^2}{m_e(m_d + m_u)} \sim \left(\frac{1\text{TeV}}{\Lambda_{eP}}\right)^2 \times 10^3$$

0.05 % Measurement $\rightarrow \Lambda_{eP} > 1000 \text{ TeV}$

Charged Higgs mass $m_{H^\pm} \sim 200 \text{ TeV}$ probed.

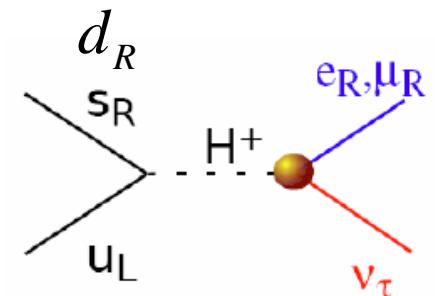

Marciano

Charged Higgs and Lepton Flavor Violation

Masiero, Paradisi, Petronzio, hep-ph/0511289 PRD74,(2006)

The unobserved neutrino involved in

$\pi^+ / K^+ \rightarrow e^+ \nu$ decay may be ν_e, ν_μ , or ν_τ .

Low Energy SUSY (with R parity*); Large $\tan \beta$.

$$R_{e/\mu}^{NP} = R_{e/\mu}^{SM} \left(1 + \Delta r_{NP}^{e/\mu} \right)$$

Current (Future) Experiments:

$$\left| \Delta r_{\pi}^{e/\mu} \right| < 0.004 \text{ (0.0003)} \quad \left| \Delta r_K^{e/\mu} \right| < 0.06 \text{ (0.005)}$$

i) FCNC $M \rightarrow l \nu_l$; $\Delta r_{NP}^{e/\mu} < 10^{-6}$

*R Parity (MSSM): $R=(-1)^{3B+L+2S}$

ii) Lepton Flavor Violation $M \rightarrow l_i \nu_k; i (= e, \mu), \neq k (= \tau)$.

$$\Delta r_{SUSY}^{e/\mu} = \left(\frac{m_P}{m_H} \right)^4 \left(\frac{m_\tau}{m_e} \right)^2 \Delta_P^{(31)} \tan^6 \beta \quad P = \pi, K$$

$$\leq O_K(0.01), \quad O_\pi(0.0003);$$

For $\Delta_P^{31} \sim 510^{-4}$, $\tan \beta \sim 40$

Effects (optimistically!) in range of planned experiments.

For the parameters above $R(\tau \rightarrow \mu\gamma) \sim 10^{-10}$;

(Present experiment (Babar/Belle) $R(\tau \rightarrow \mu/e\gamma) < 10^{-7}$.)

Larger effects in $B \rightarrow l\nu$, beyond reach of current experiments.

Scalar Interactions:

$\pi \rightarrow e\nu$ vs. Super-allowed β Decay

$$\left. \begin{array}{l} \text{CKM Unitarity: } |V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9992(10) \\ R_{e/\mu} = \frac{\Gamma(\pi^+ \rightarrow e^+ \nu(\gamma))}{\Gamma(\pi^+ \rightarrow \mu^+ \nu(\gamma))} = 1.231(4) \times 10^{-4} \text{ (now } \rightarrow < 0.1\%) \end{array} \right\} 0.1\% \text{ Precision}$$

Constraining new Physics?

Direct Constraints

$$R_{e/\mu} : \quad \Lambda_A \sim 20 \text{TeV}, \quad \Lambda_P \sim 1000 \text{TeV} (!)$$

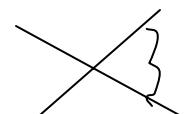

$$SM : \frac{G_\mu}{\sqrt{2}} \sim \frac{\pi}{2\Lambda_{SM}^2}; \quad \Lambda_{SM} \sim 440 \text{GeV}$$

$$\text{Unitarity: } \quad \Lambda_V \sim 20 \text{TeV}, \quad \Lambda_S \sim 12 \text{ TeV}$$

Induced Current Constraints

$$R_{e/\mu} : \quad \Lambda_V \sim 2 \text{TeV}, \quad \Lambda_S \sim 60 \text{TeV} (!)$$

$$\text{Unitarity: } \quad \Lambda_A \sim 2 \text{TeV}$$

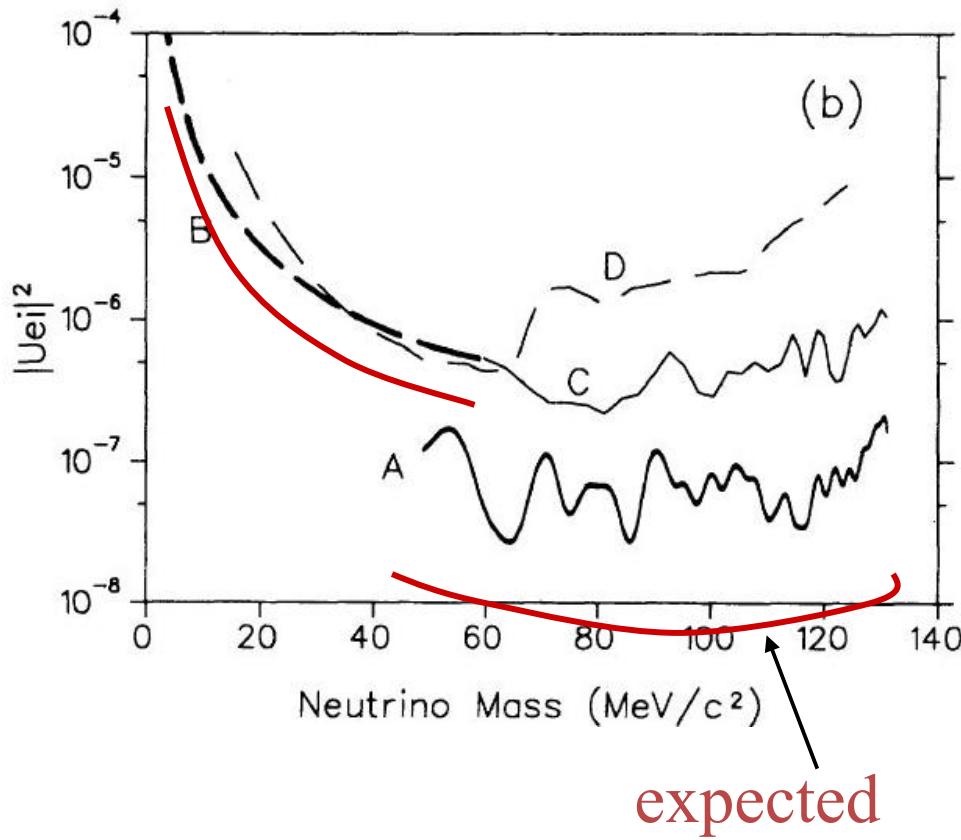

Loops 
 e.g. A induces V
 P induces S

$$\pi / K^+ \rightarrow e^+ \nu$$

Other New Physics Possibilities:

SM extensions:

Heavy ν

-Leptoquarks

-Excited gauge bosons

-Compositeness

-*R-parity violating SUSY*

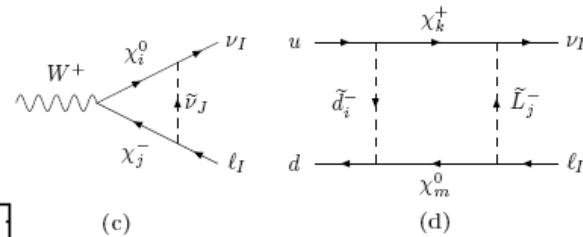

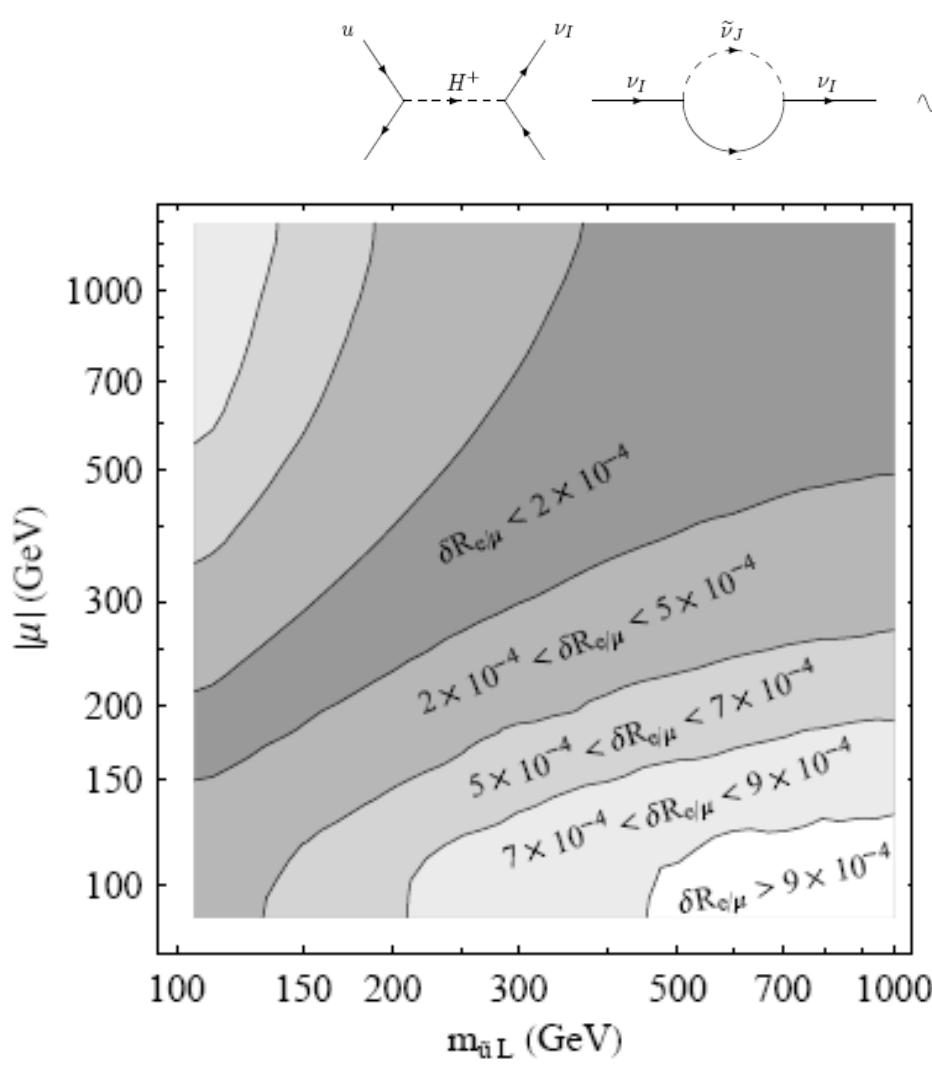

-Extra dimensions

- ν Mass from QCD cond.
(Davoudias,Everett (2006))

- LFV (Isidori, Paradisi (2006))

$\pi^+ \rightarrow e^+ \nu$ Sensitive to R-Parity Violating MSSM

Ramsey-Musolf, Su, Tulin, arXiv:0705.0028 (2007)

μ vs. $m_{\tilde{u}_L}$
 μ : Higgsino mass parameter
 $m_{\tilde{u}_L}$: Mass of \tilde{u}_L

R Parity (MSSM): $R=(-1)^{3B+L+2S}$

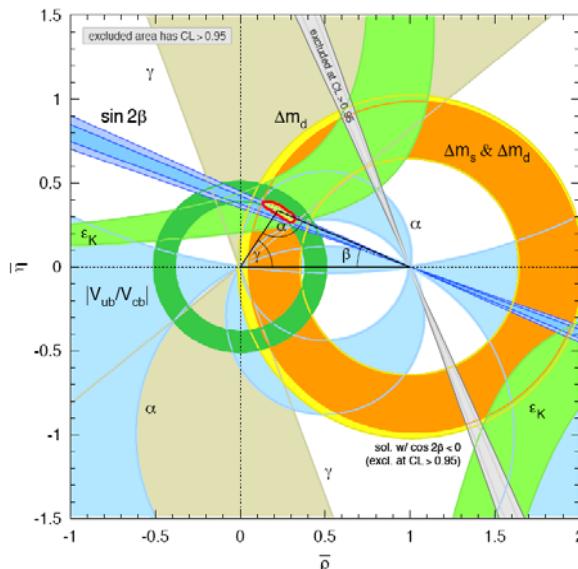

Quark Mixing: SM works well at the Electroweak Scale

$$L_{SM} = L_{Gauge} + L_{Higgs}(\phi_i, A_i, \psi_i, Y, v)$$

Flavor degeneracy broken by Yukawa couplings
CKM quark mixing matrix:

$$V_{CKM} \approx \begin{bmatrix} 1-\lambda^2/2 & \lambda & A\lambda^3(p-i\eta) \\ -\lambda & 1-\lambda^2/2 & A\lambda^2 \\ A\lambda^3(1-p-i\eta) & -A\lambda^2 & 1 \end{bmatrix}$$

Wolfenstein parameterization

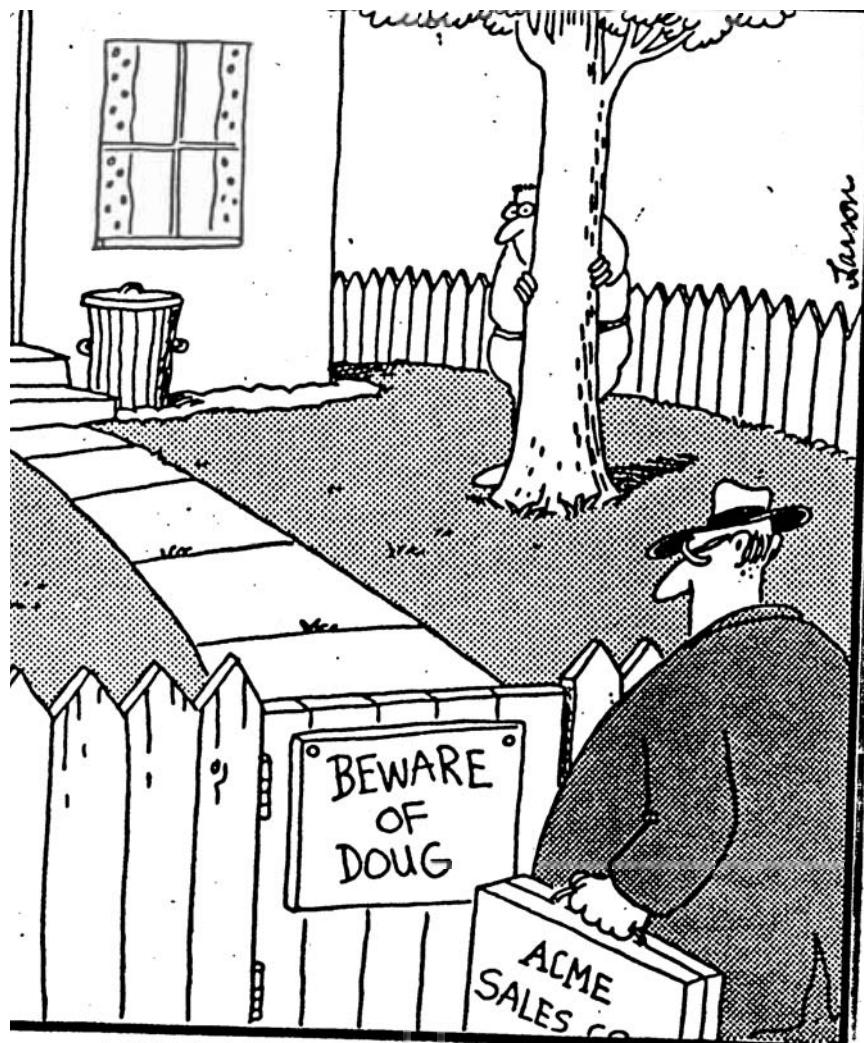

Review of Particle Prop. 2006

$$K^+ \rightarrow \pi^+ \bar{\nu\nu}$$

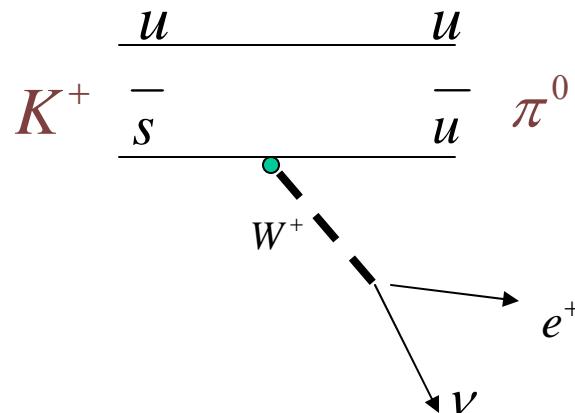

FCNC!

The case of the dog
that didn't bark.

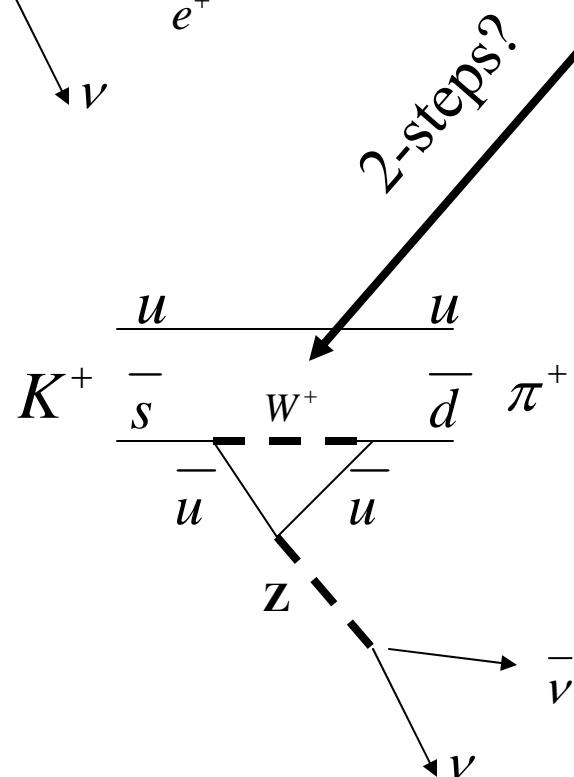

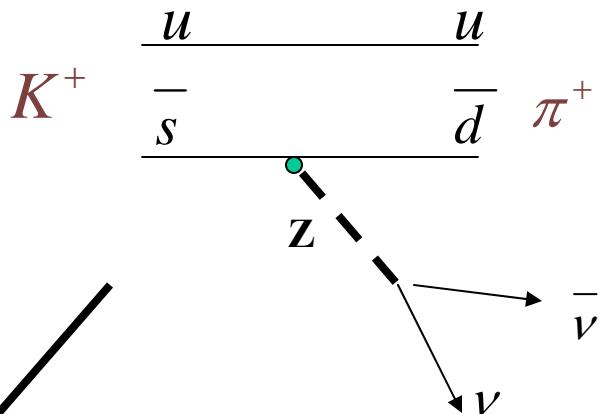

Kaon Milestones:*The G.I.M. Mechanism and Flavor-Changing Neutral Currents:*

OBSERVED: $K^+ \rightarrow \pi^0 e^+ \nu$

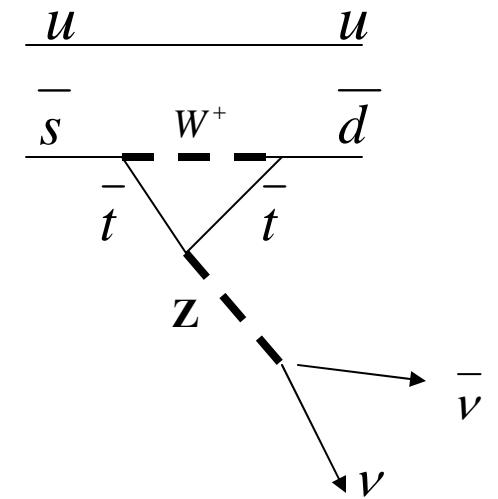

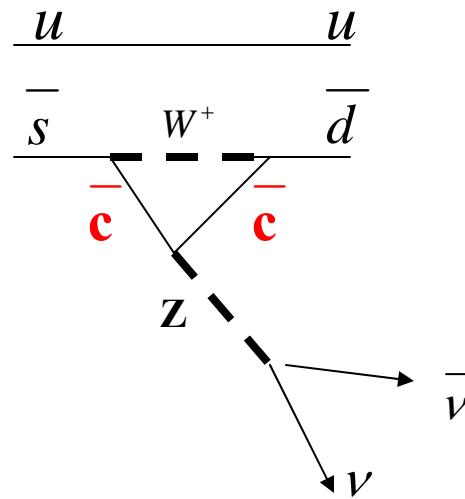

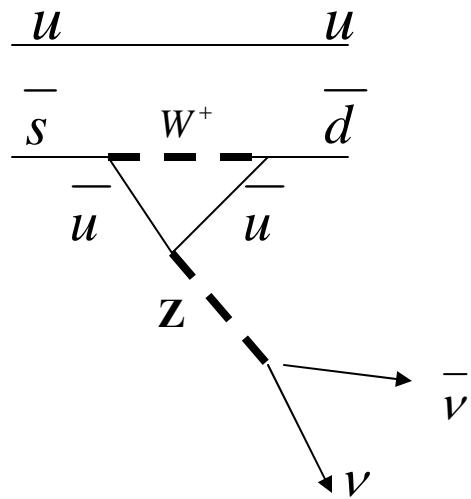

ABSENT: $K^+ \rightarrow \pi^+ \nu \bar{\nu}$

*So, why
wasn't it
observed?*

Glashow, Iopolis, Miani “invented” the c quark to solve the problem:

$$V_{us}^* V_{ud} + V_{cs}^* V_{cd} + V_{ts}^* V_{td} = 0$$

Perfect cancellation only if

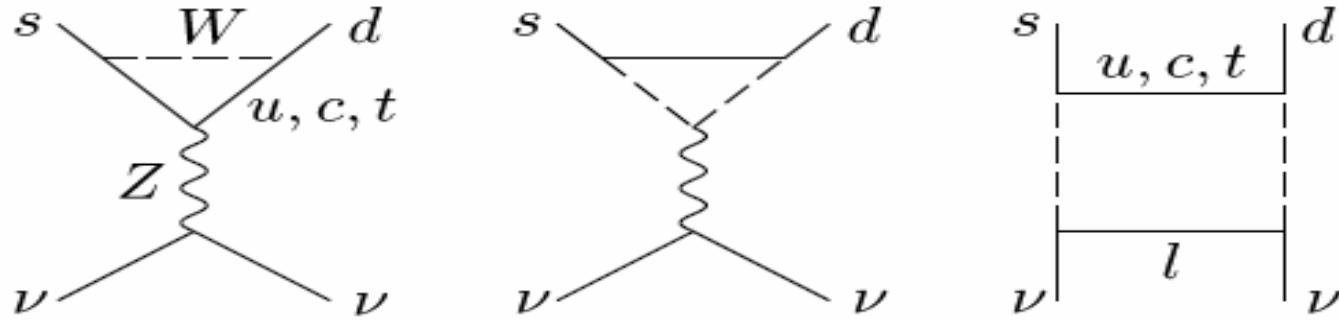

$$m_u = m_c = m_t$$

(0.0005, 1.5, 170 GeV)

$K^+ \rightarrow \pi^+ \nu \bar{\nu}$
should exist!

$K \rightarrow \pi \nu \bar{\nu}$ in the SM

"Jarlskog CP-violation parameter":

$$\text{Im } \lambda_t = \text{Im } V_{ts}^* V_{td} = \eta A^2 \lambda^5$$

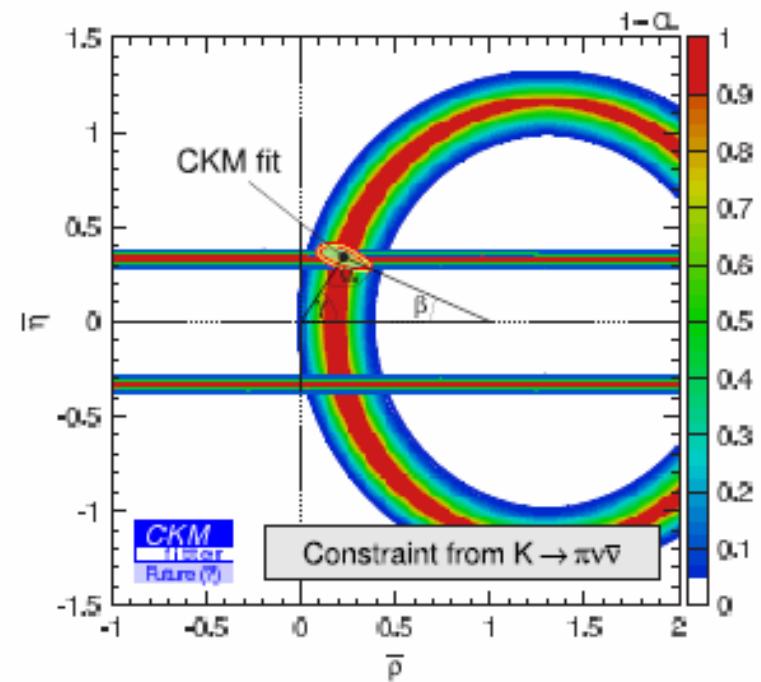

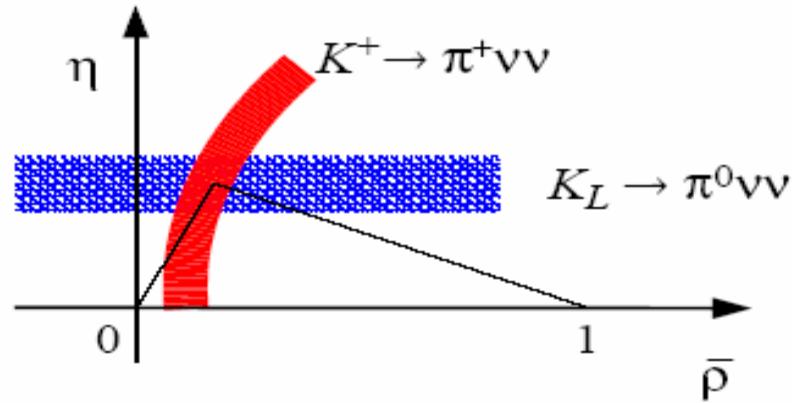

Precise SM Calculations (*Buras, et al.*):

$$B(K_L^0 \rightarrow \pi^0 \nu \bar{\nu}) = 1.8 \times 10^{-10} \left(\frac{\text{Im } \lambda_t}{\lambda^5} X(x_t) \right)^2 = 3.0 \pm 0.6 \times 10^{-11}$$

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) \sim 1.0 \times 10^{-10} A^4 \left[\eta^2 + (\rho_0 - \rho)^2 \right] = 7.8 \pm 1.2 \times 10^{-11}$$

K^+ uncertainty: m_c

$$\text{Golden Relation: } \sin(2\beta)_{\psi K_S} = \sin(2\beta)_{K \rightarrow \pi \bar{\nu}\nu}$$

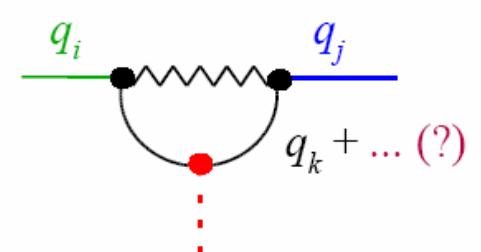

Constraints from 10% Measurements of $K \rightarrow \pi \bar{\nu}\nu$
 (J.Charles et al., hep-ph/0406184, Eur. Phys. J. C41, 1 (2005), <http://ckmfitter.in2p3.fr/> .

Rare Decays play key roles for SM parameters e.g. V_{us} .

Even more important:
Probing the flavor structure of ‘new physics’.

Special Case : $K_L^0 \rightarrow \pi^0 \nu \bar{\nu}$

- Dominated by direct CP violation in amplitude $q_i \rightarrow q_j + \nu \bar{\nu}$
- (K-K mixing effects negligible)
- Dominated by short distance physics
- No tree level contributions
- Suppressed by CKM hierarchy
- *Yield precise determination of CKM CPV phase*

- SM**
- Still dominated by short distance physics!
 - Still dominated by direct CP violation in amplitude.
 - Unique access to new CP-violating phases

New Physics: *Model-Independent Description* (Buras, Isidori, et al.)

L_{SM} ~ Renormalizable part of an effective F. T. :

$$L_{EFT} = L_{SM} + \Sigma \frac{\lambda}{\Lambda^2}$$

Main Issues: Cutoff scale Λ [TeV], Symmetries

**Rare K Decays can probe the flavor structure
of the new physics at very high mass scales.**

For measurement precision $P = \frac{\sigma(B)}{B_{SM}(K_L^0 \rightarrow \pi^0 \nu \bar{\nu})} :$

$$\frac{\Lambda}{\sqrt{\text{Im } \lambda_{sd}}} > \frac{405}{\sqrt{P}} \text{ TeV (90% C.L.)}$$

$$\xrightarrow{P=0.1} 1280 \text{ TeV!}$$

Most pessimistic new physics scenario:

"Minimal Flavor Violation"

(Examples: Low energy SUSY, univ. extra dimensions,...)

$\Lambda \sim \text{TeV}$

Breaking of flavor symmetry occurs at very high scales

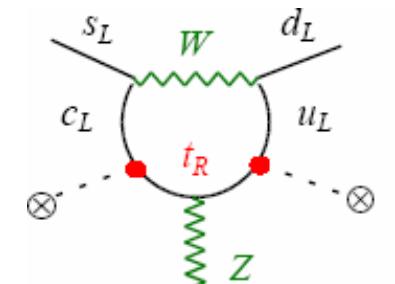

- mediated at low energies by terms proportional to
SM Yukawa couplings.

Only small deviations likely (at LHC or in rare decays)

But new CP-violating phases are naturally present.

$K_L^0 \rightarrow \pi^0 \nu \bar{\nu}$ still sensitive O(50%) whereas

previously clean SM observables (e.g. asymmetries in non-leptonic B decays) are no longer clean or not generally sensitive to new physics in decay amplitudes.

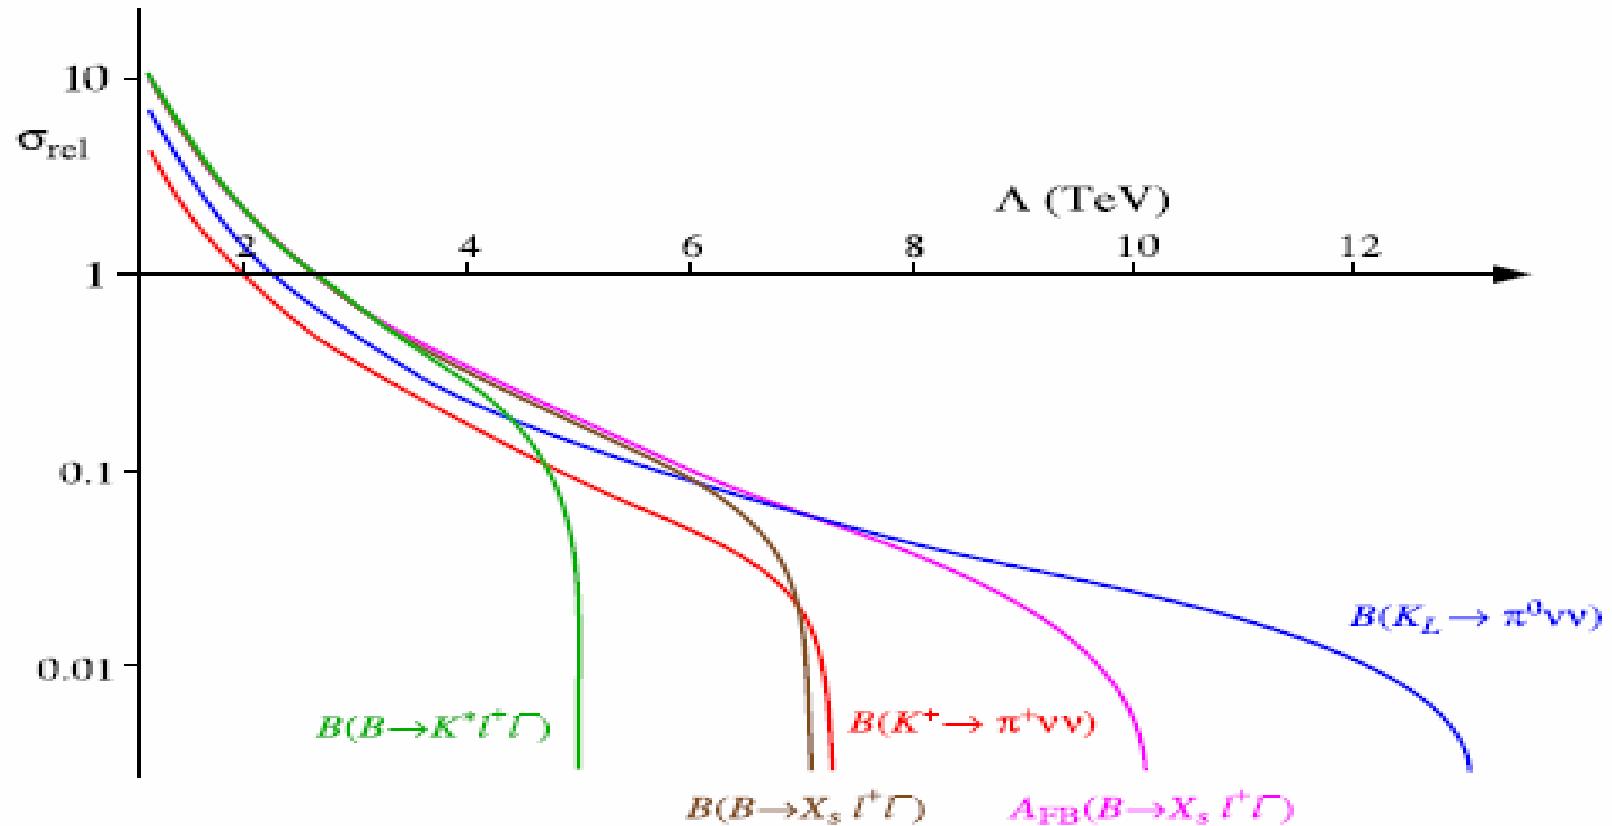

10% measurement of $K_L^0 \rightarrow \pi^0 \nu \bar{\nu}$ probes EW-Yukawa structure at the 5% level -- only a high luminosity linear collider could do better. [G. Isidori]

Comparative Sensitivity to New Physics in the ‘Minimal Flavor Violation’ Scenario

Precision

$\Lambda \sim \text{TeV}$

D'Ambrosio et al. 2002

New Physics: 1-10 TeV Scale

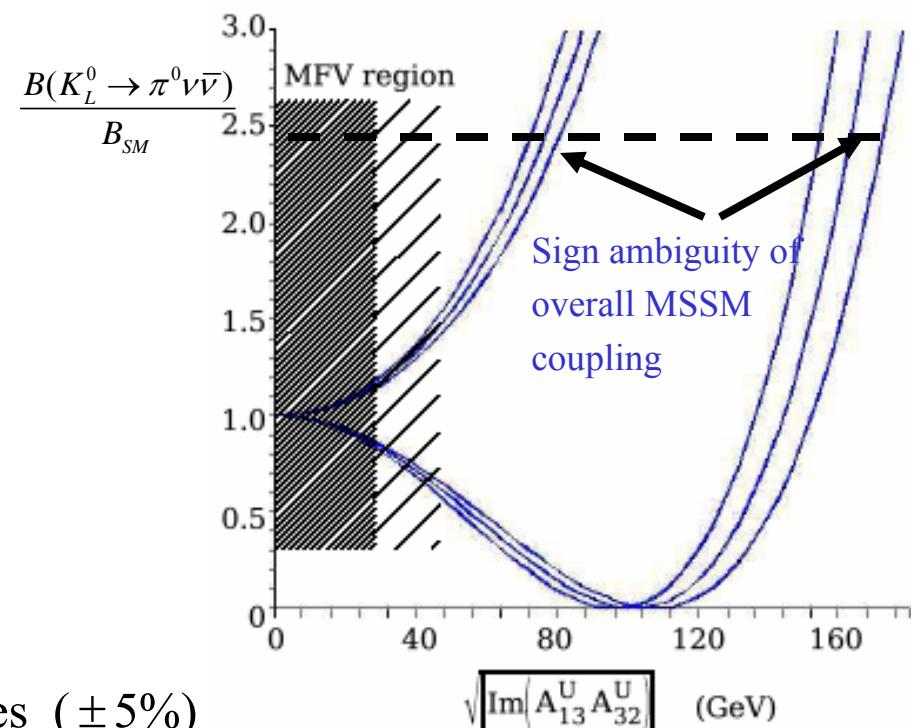

Example: MSSM with generic flavor couplings

- Challenged by precise SM results in B physics
- *But, large portion of the parameter space unexplored*
- *New sources of CP violation possible*
- Discovery at LHC?: masses, dominant couplings
- *Rare decays: New Effects of CP violation, flavor mixing*

squark and chargino masses ($\pm 5\%$)

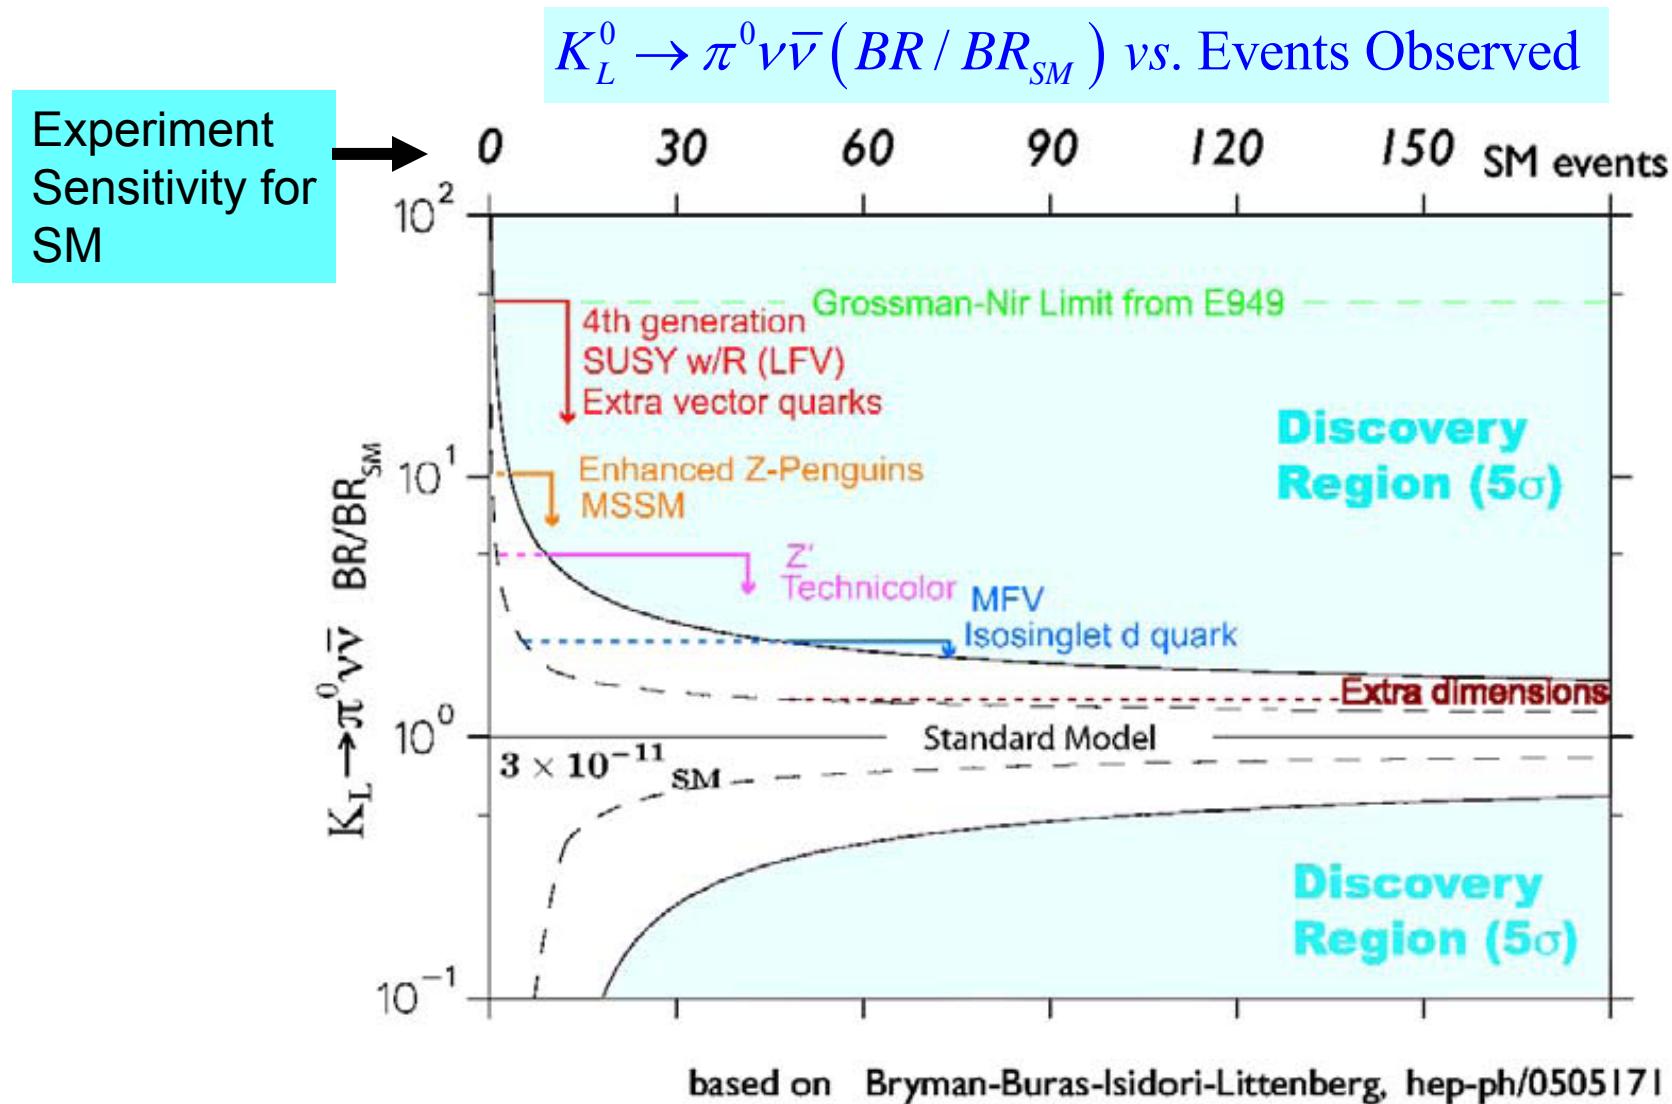

$$\tilde{m}_L = 500 \text{ GeV} \quad \tilde{m}_R = 300 \text{ GeV}$$

$$\tilde{m}_{\chi^\pm} = 200 \text{ GeV}$$

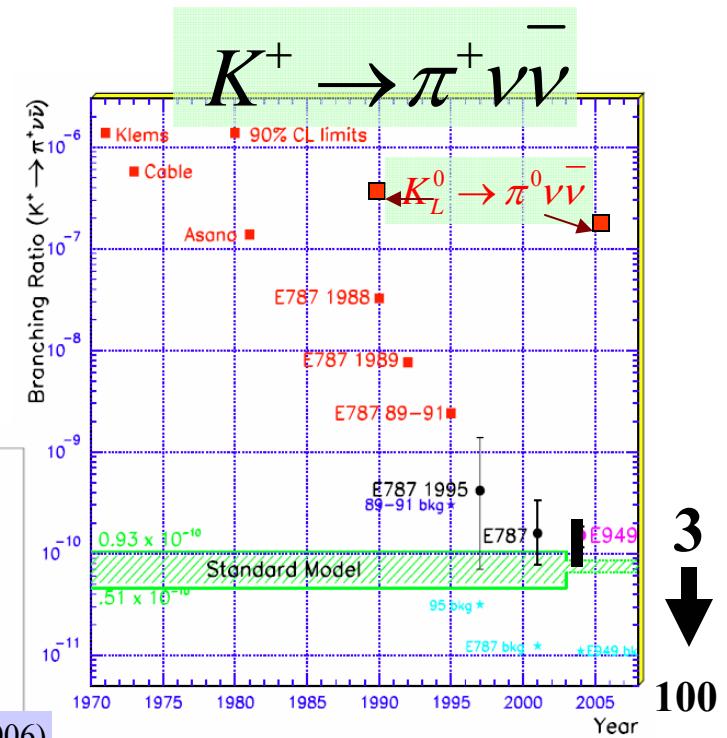

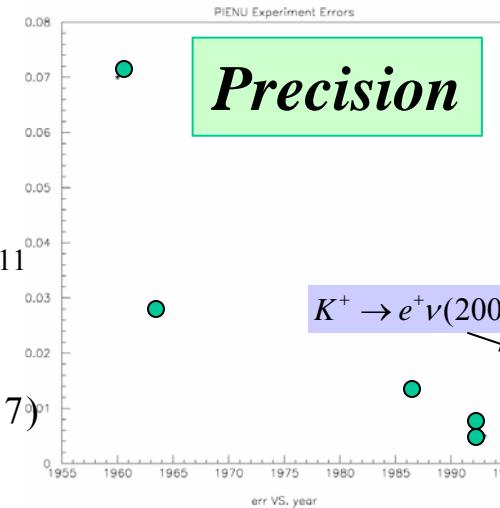

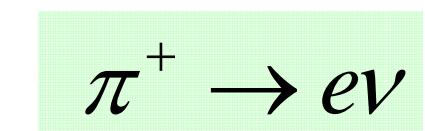

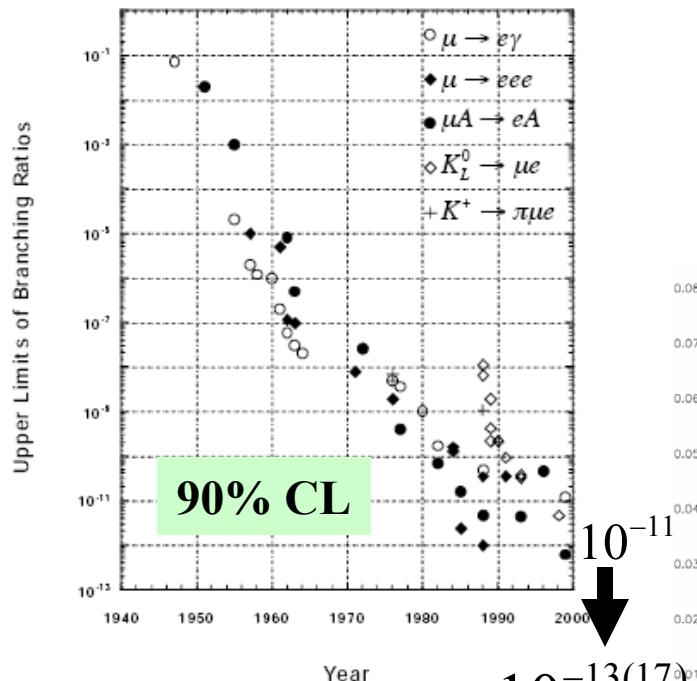

Soft breaking trilinear couplings
squark & chargino masses fixed

$K_L^0 \rightarrow \pi^0 \nu \bar{\nu}$ Discovery Potential

Experiments

Lepton Flavor Violation

0.04%

0.4%

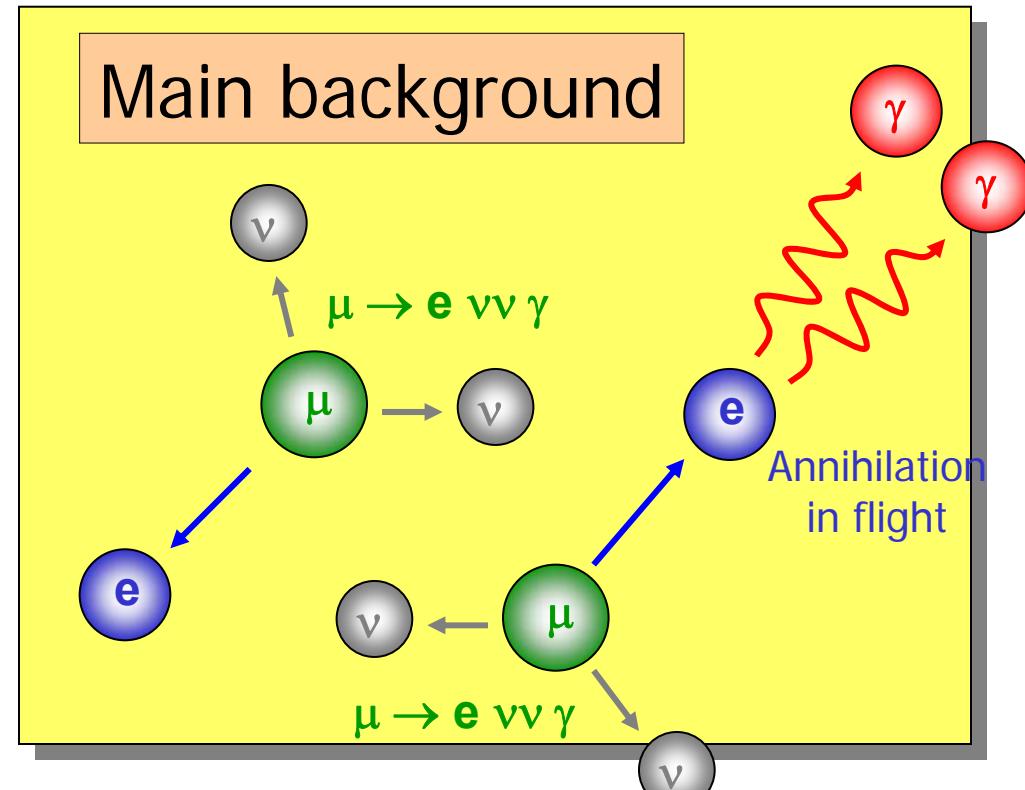

$10^{-13}(17)$

Decay topology

$\mu \rightarrow e \gamma$ signal very clean

- $E_g = E_e = 52.8$ MeV
- $\theta_{\gamma e} = 180^\circ$
- e and γ in time

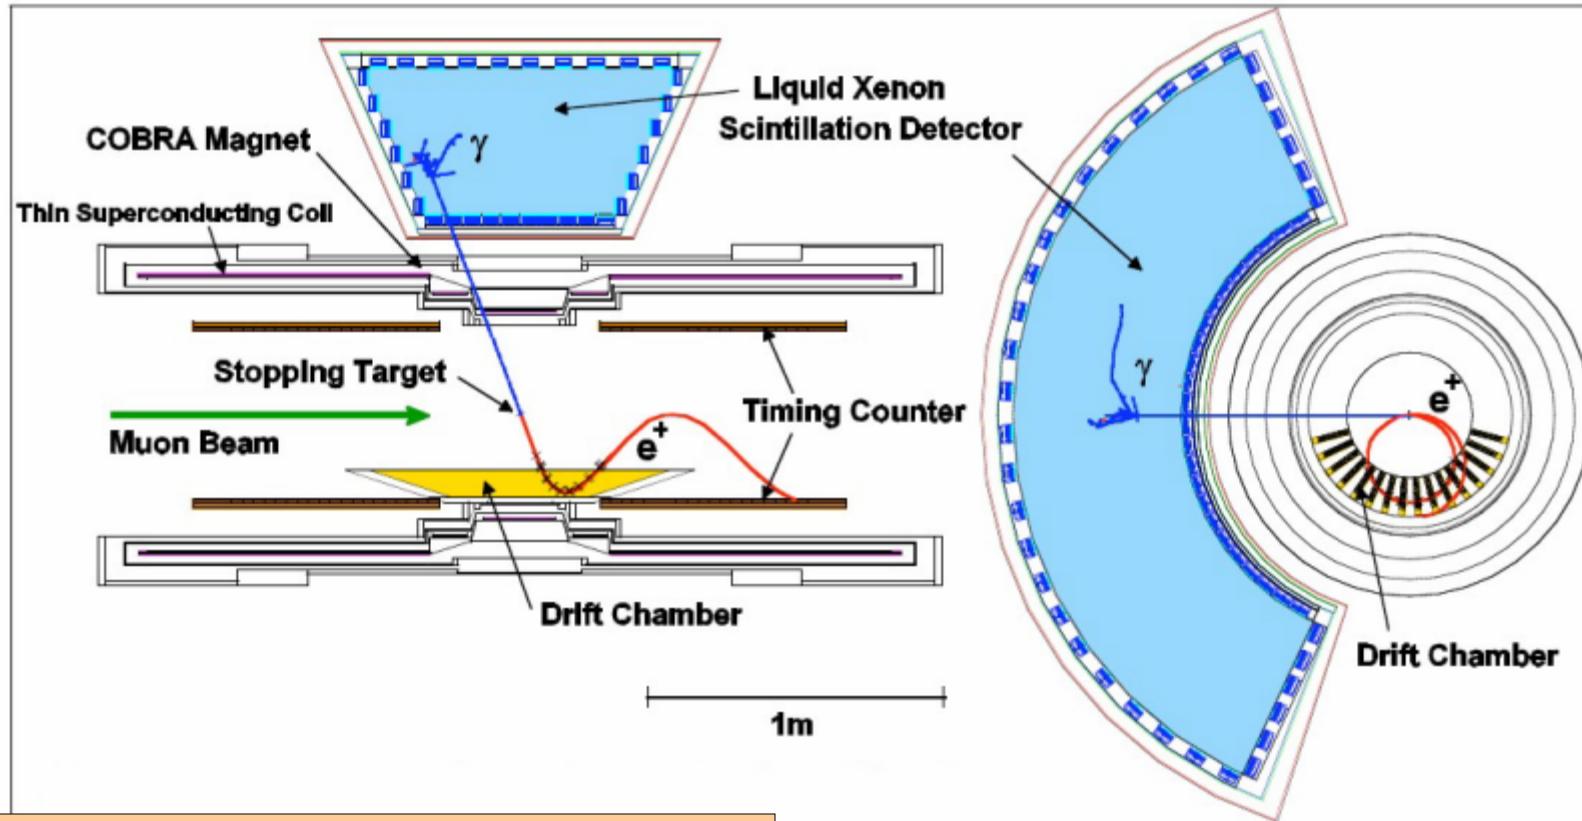

Background: Energy, spatial, timing resolutions
Good pile-up rejection

$$\Delta B(\mu \rightarrow e\gamma) = \left(\frac{R_\mu}{d} \Delta t \right) \left(\frac{\Delta E_e}{m_\mu/2} \right) \left(\frac{\Delta E_\gamma}{15m_\mu/2} \right)^2 \left(\frac{\Delta \theta}{2} \right)^2 f(\theta_\gamma) \eta_{IVB}$$

$\mu \rightarrow e \gamma$

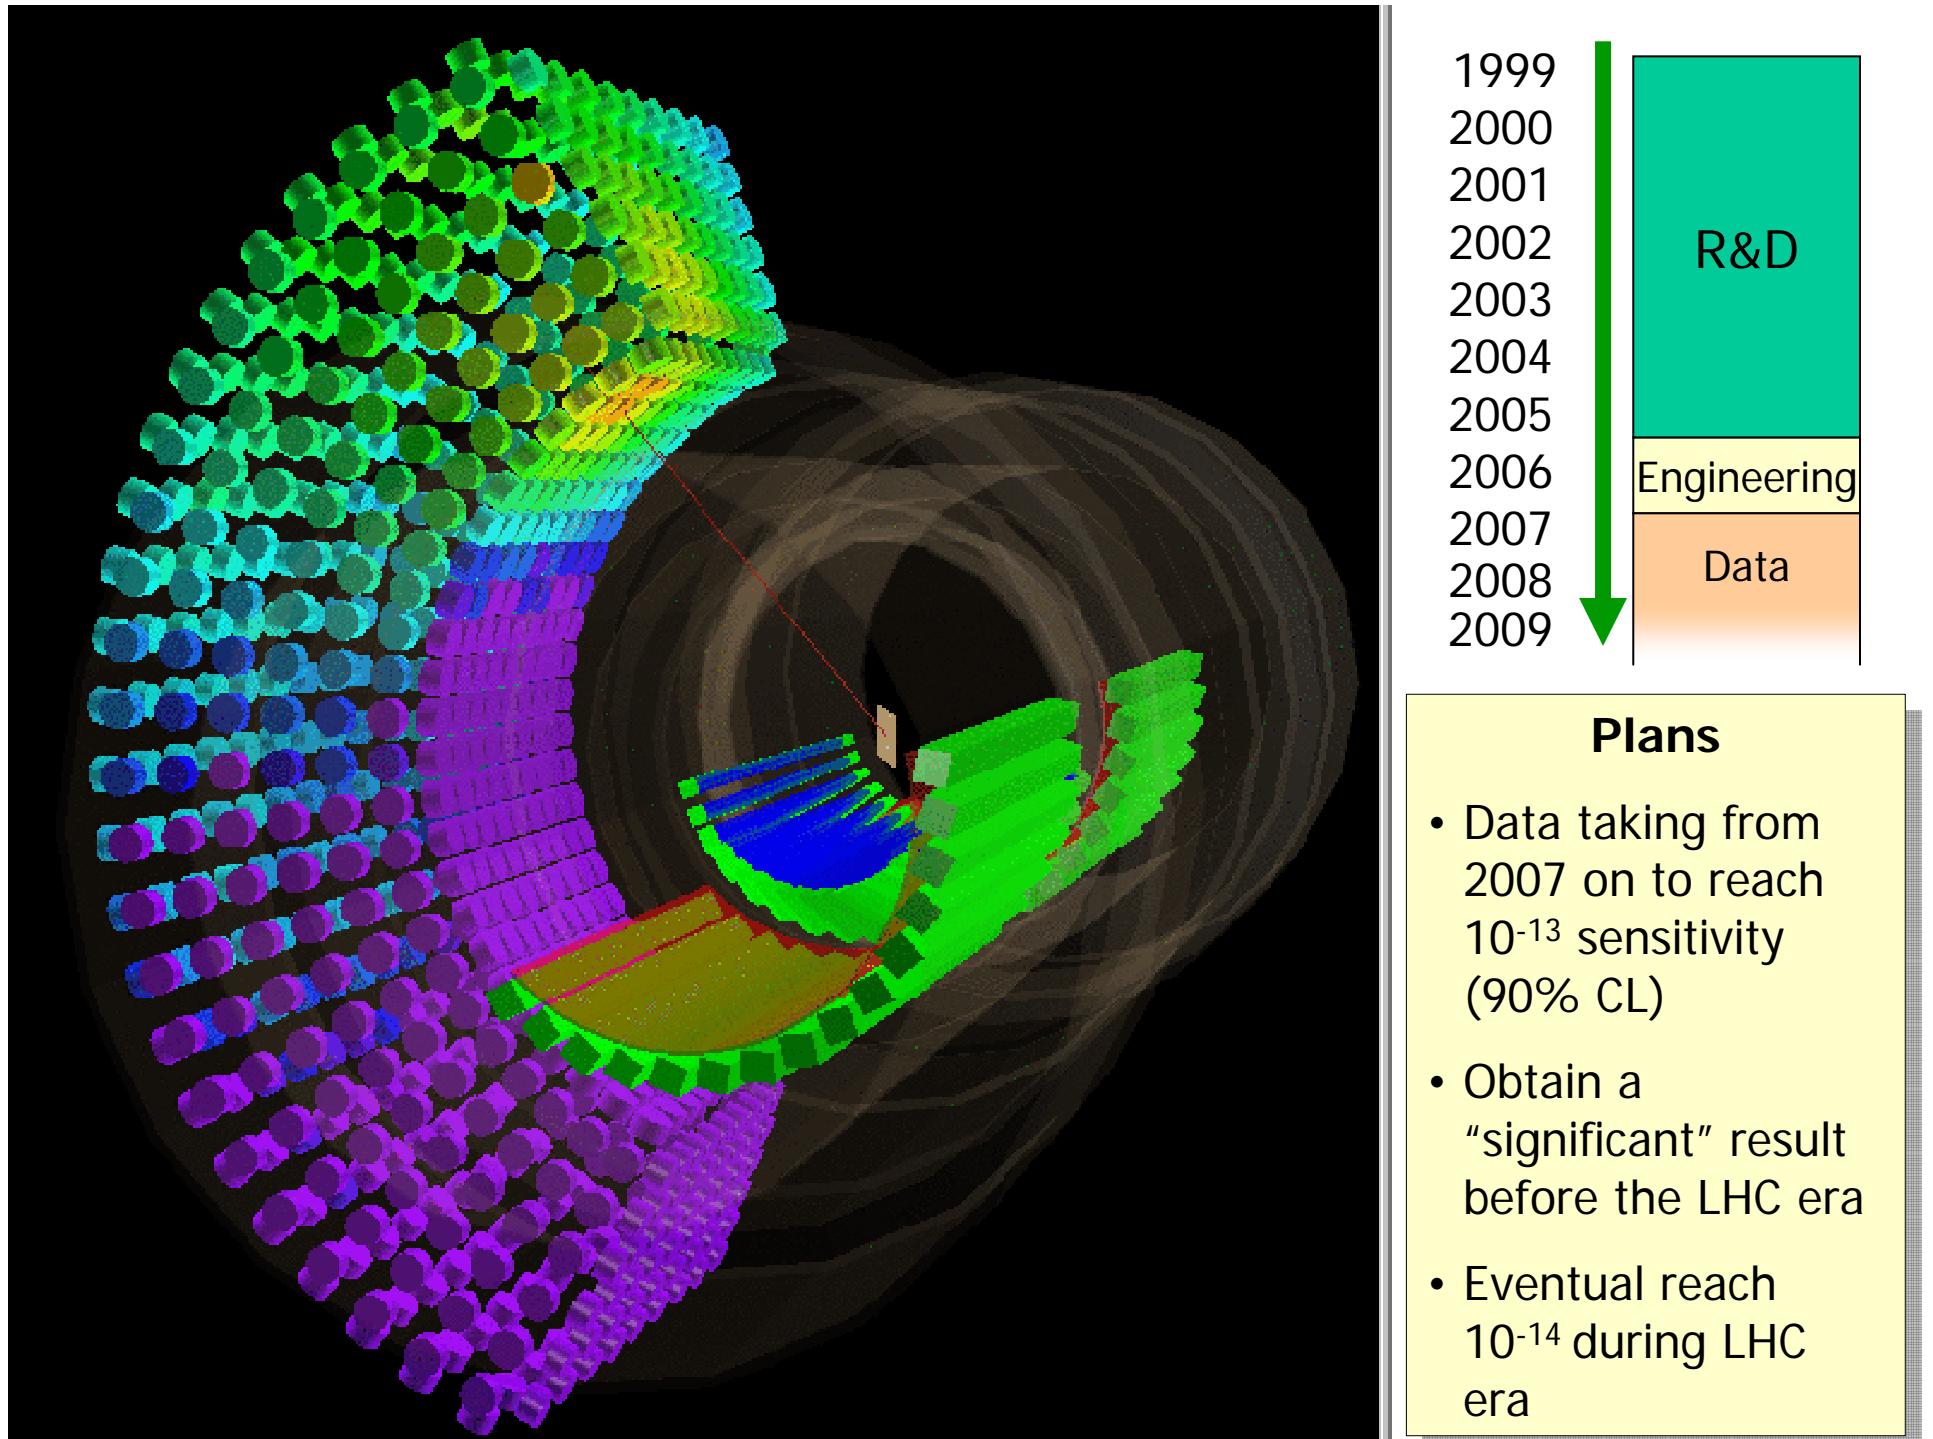

MEG Experiment at PSI

Goal (limit) $< 1.3 \cdot 10^{-13}$ (0.01 x prev. exp)

- $10^7 - 10^8 \mu/\text{sec}$, 100% duty factor
- LXe for efficient γ detection
- Solenoidal magnetic spectrometer

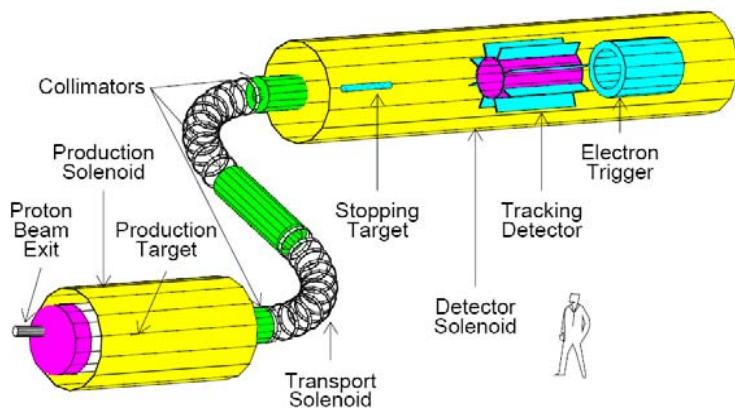

Limitations: Accidental coincidences.

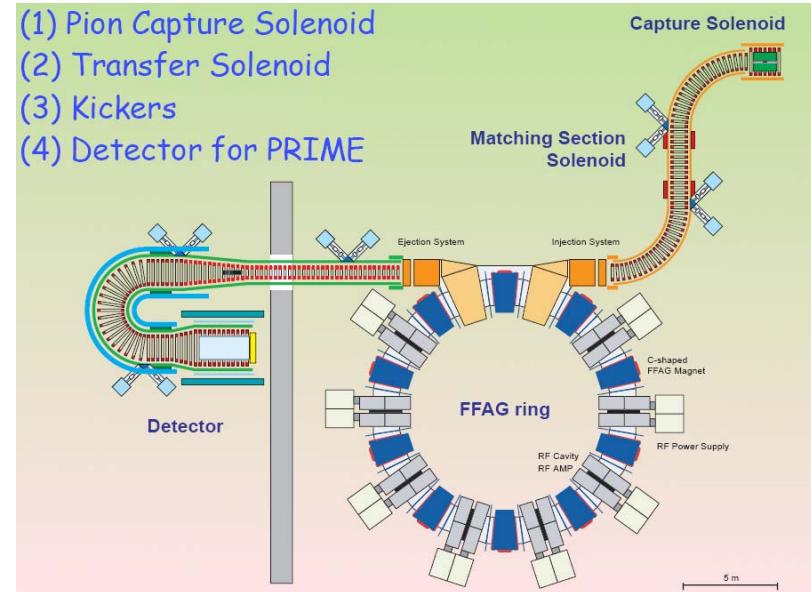

$\mu^- N \rightarrow e^- N$ Concepts: Sensitivity $< 10^{-17}$

Lobashov (1980): Solenoidal Pion Collector; μ Flux x 1000.

MECO proposal

PRISM Concept (JPARC LOI Cooled beam (Kuno)

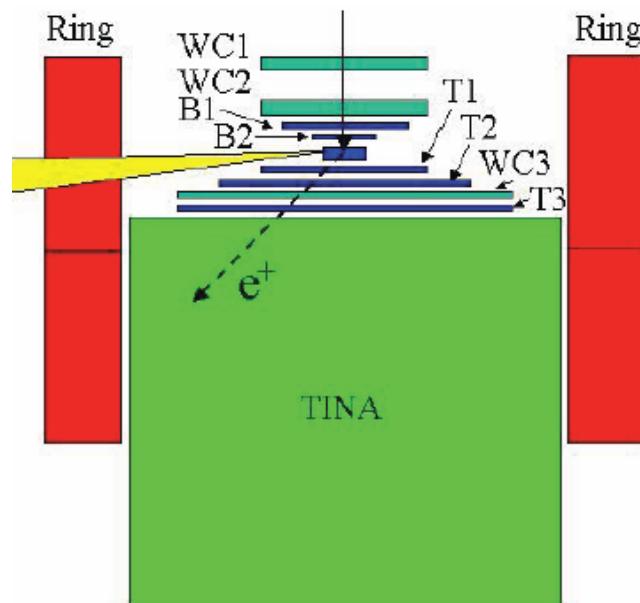

- Singles experiment – not limited by accidentals
- Background (decay-in-orbit) known and calculable.
- High resolution detector feasible.

New $\pi^+ \rightarrow e^+ \nu$ Experiments

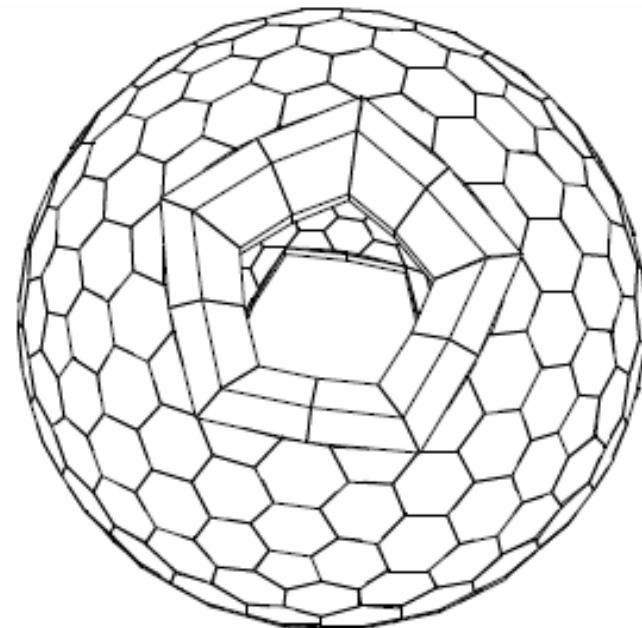

Precision Goals for $R_{e/\mu}^{\exp\pi} : < 0.1\%$

TRIUMF PIENU

ASU, BNL, Osaka, TRIUMF, UBC, VPI

PSI PIBETA Spectrometer

INS (Pol.), IHEP, JINR,
PSI, RBI, Virginia, Zurich

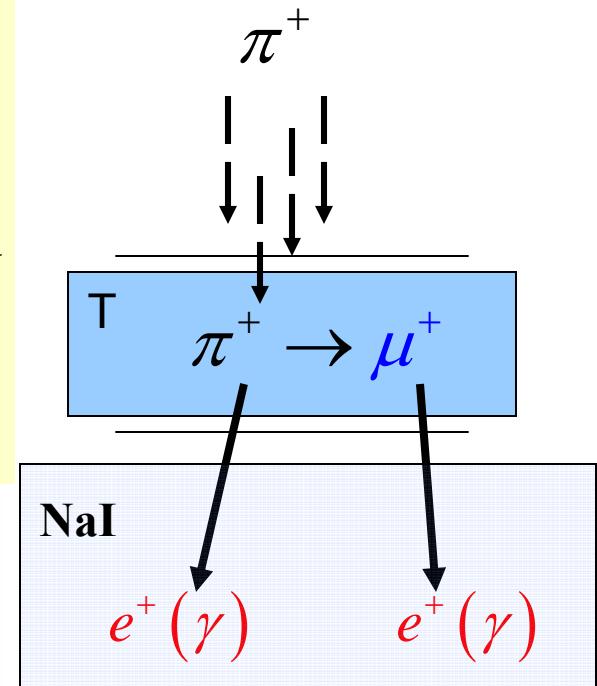

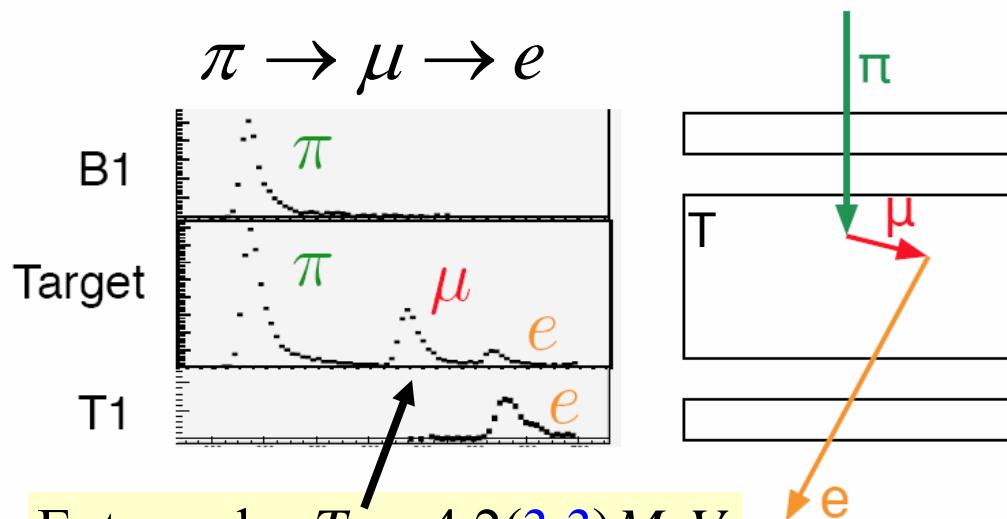

PI E NU

Experiment Concepts

Low Momentum π Beam at $p=75$ MeV/c.

π s lose energy and stop in a target of plastic scintillator (T). Scintillation detectors viewed by photo-multiplier tubes and all signals are digitized at 500 MHz.

$$\tau_\pi = 26\text{ns}, \tau_\mu = 2200\text{ns}$$

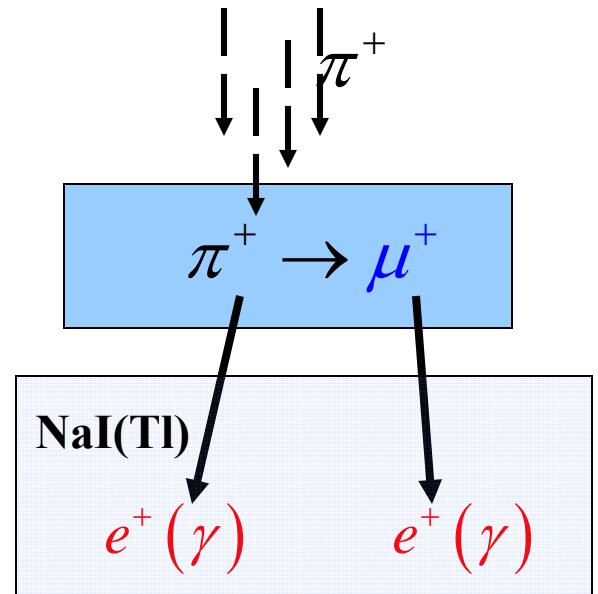

Measure positron energies in a NaI(Tl) crystal spectrometer (no magnetic field!):

$$[\pi^+ \rightarrow e^+ \nu] \quad P_e = 70 \text{ MeV} / c$$

$$[\pi^+ \rightarrow \mu^+ \nu] \quad P_\mu = 30 \text{ MeV} / c$$

$$T_\mu = 4.2 \text{ MeV}, R_\mu = 1.4 \text{ mm}$$

$$[\mu \rightarrow e^+ \nu \bar{\nu}] \quad P_e = 0 - 53 \text{ MeV}$$

Electrons have fairly uniform interactions over the range $P[1-70 \text{ MeV}]$:

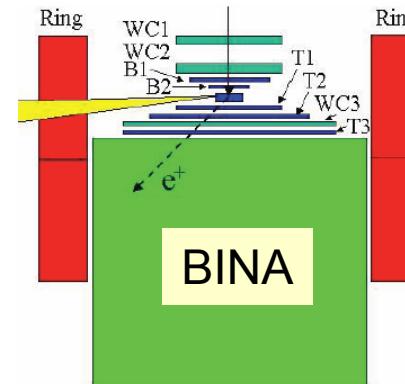

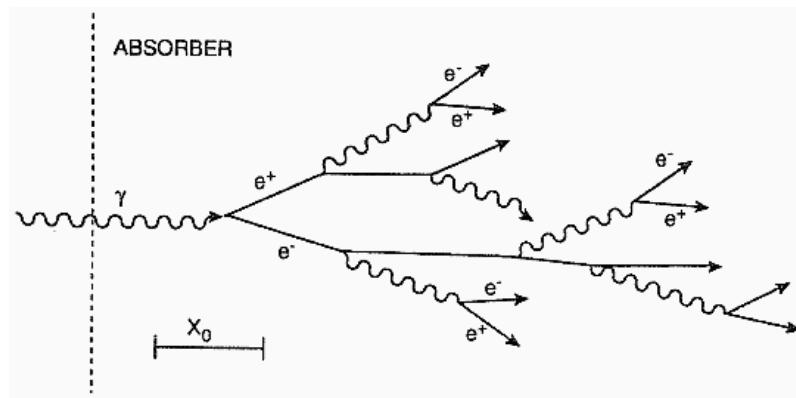

Systematic effects cancel (to 1st order) in the ratio $\frac{\Gamma(\pi \rightarrow e)}{\Gamma(\pi \rightarrow \mu \rightarrow e)}$

e.g. solid angle, Multiple Coulomb Scattering, $\frac{dE}{dx}$, annihilation, bremsstrahlung, timing.

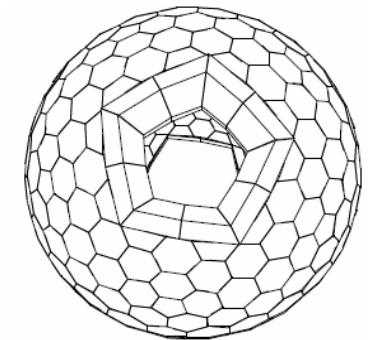

N.B.: When aiming for high precision: must rely on measurements for corrections rather than simulations whenever possible!

Detector build-up

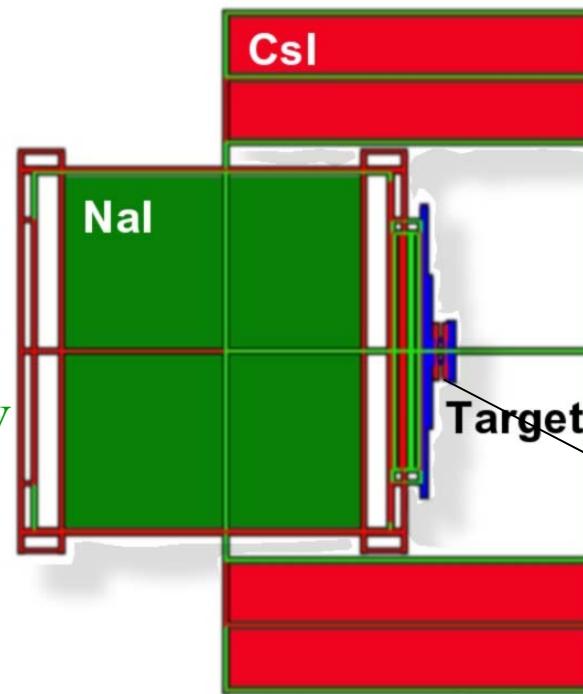

**Brookhaven NaI crystal
(BINA)**

Radius=24 cm

Length = 48 cm(19 X_0)

Energy resolution:

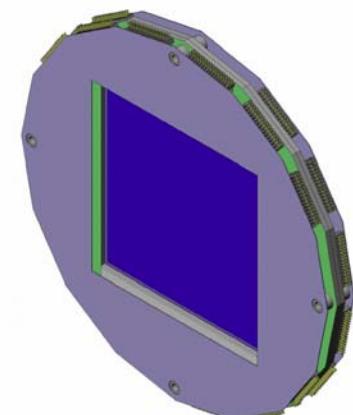

$\sim 2\%$ (FWHM) at 70 MeV

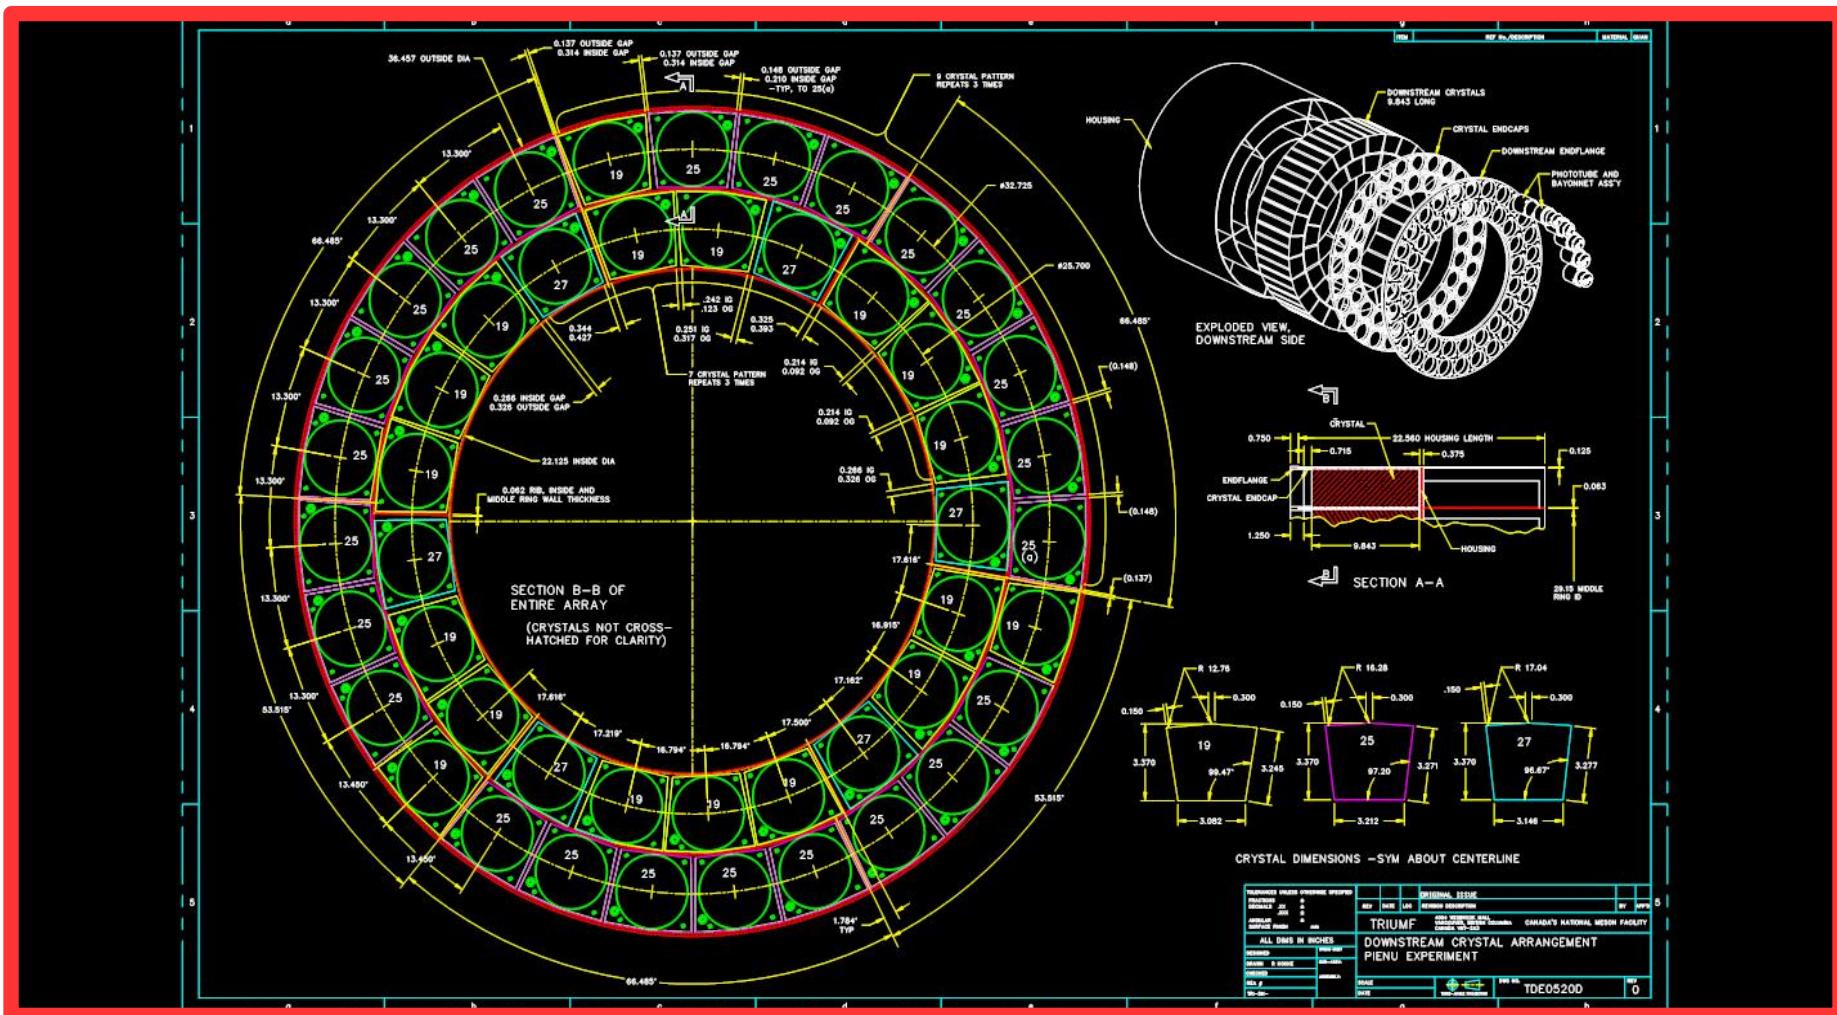

Pure CsI crystals

π Beam

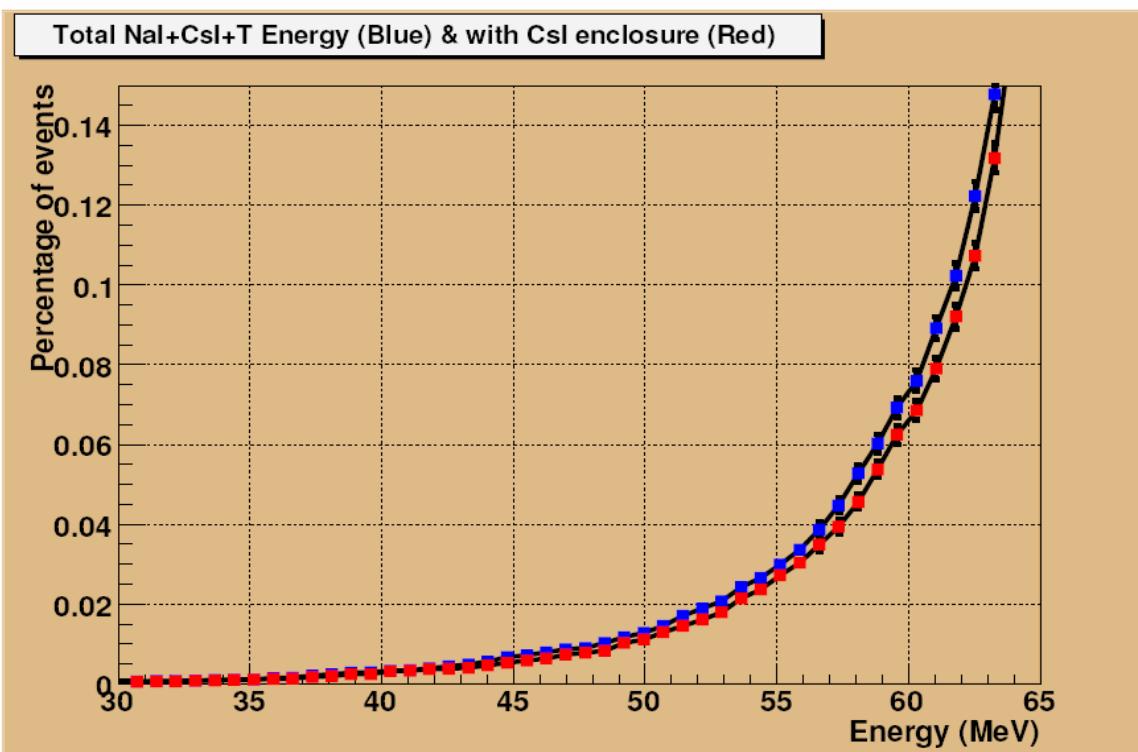

**Si Strips
300 (80) μm pitch**

CsI enclosure

To reach 0.05% precision, everything must be studied/known to 0.01%: GEANT3 & 4 MC Studies Example:
Dead material and Gaps between crystals

Support material in gaps between crystals: <10% effect, known to <1% precision.

From analysis of the Beam Test data:

Pulse fitting

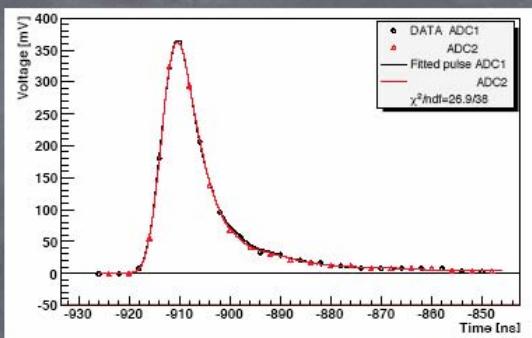

Fitting as a single pulse

Fitting function

2 free parameters A1,T1

$$V=A_1 F(t+T_1)$$

for B1,B2,T1,T2

Fitting as a double pulse

Fitting function

4 free parameters A_i,T_i i=1,2

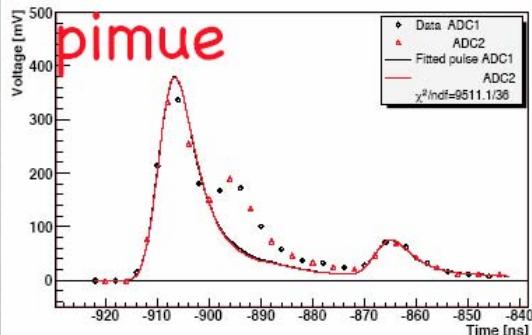

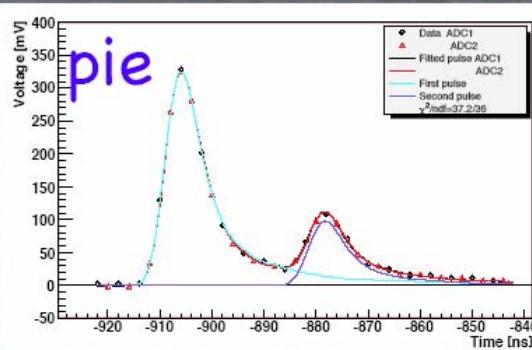

$$V=A_1 F(t+T_1)+A_2 F(t+T_2)$$

for Target

pie->correct assumption

pimue->incorrect assumption

χ^2 and parameters obtained
from fitting is useful
for identification of the decay-mode

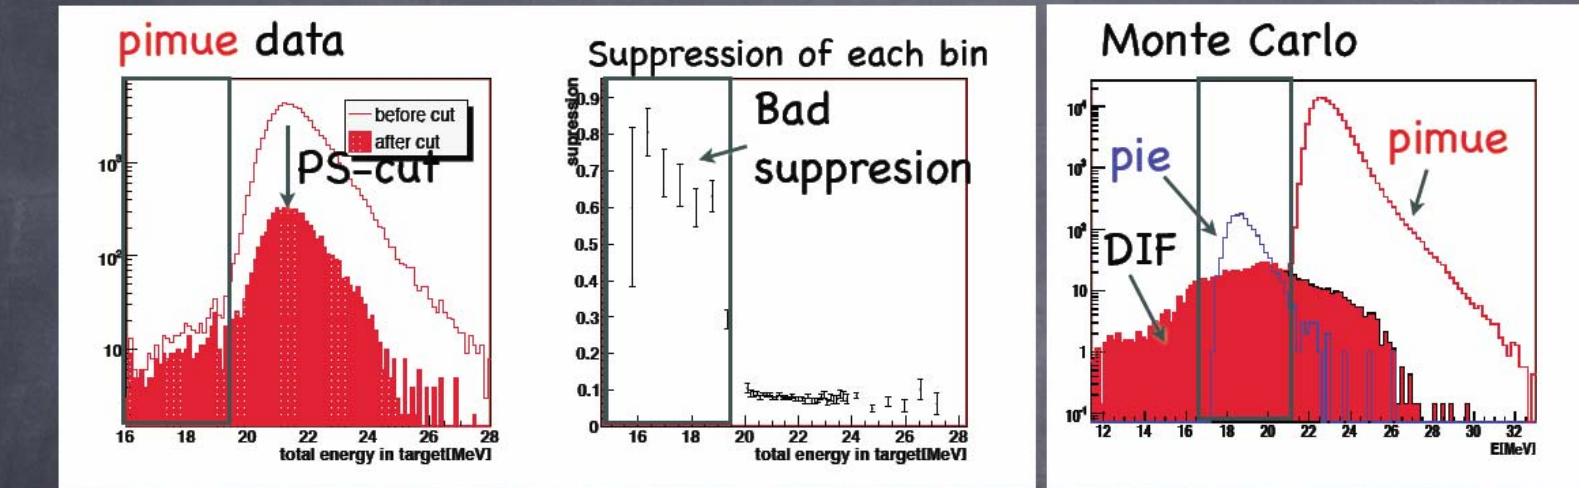

From analysis of the Beam Test data:

Decays in Flight

Correlation between E_{total} and PS-cut

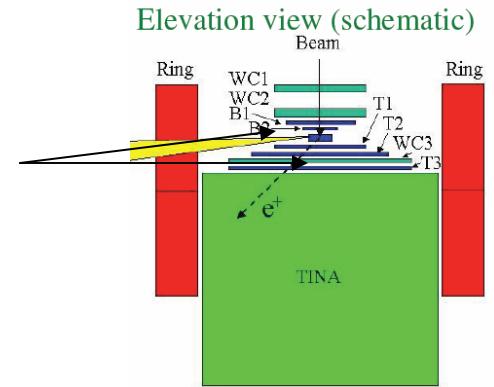

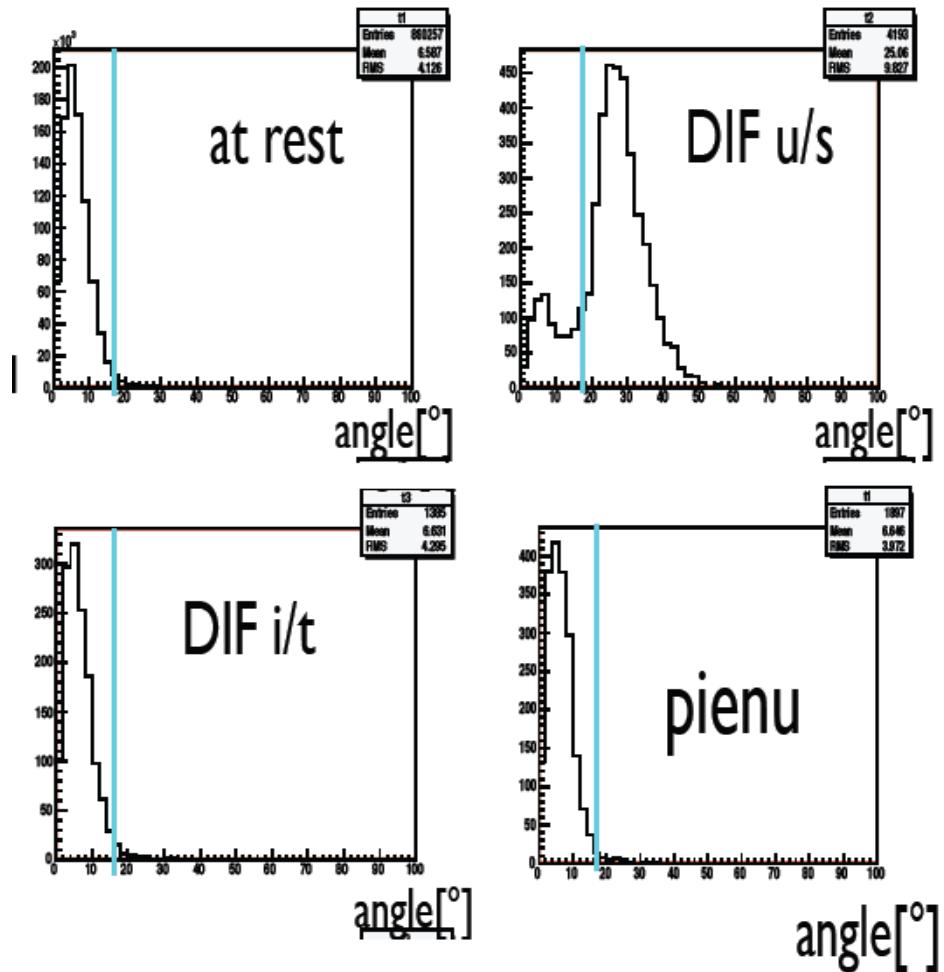

Horizontal axis: E_{total} In Target

$E_{\text{total}} < 20 \text{ MeV}$: Suppression of PS-cut is weak

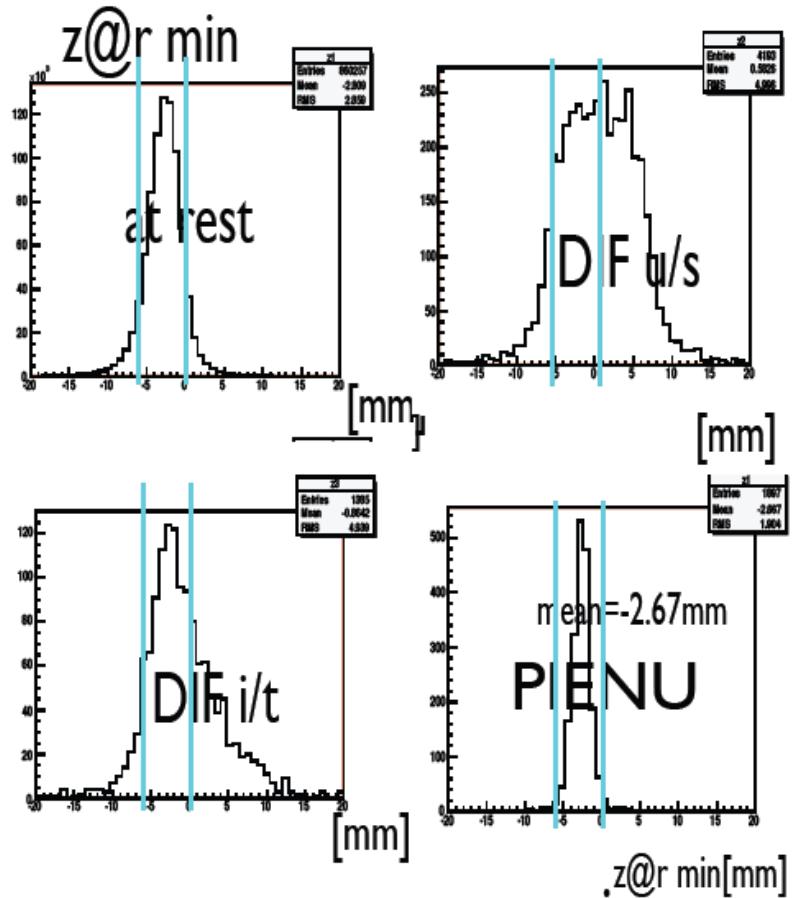

↓
DIF is dominant

Si Strip and WC tracking helps veto decays in flight

Measuring the angle between the incident beam pion (using WC) and the charged particle entering the target (using Silicon Strip detectors) helps in significantly reducing decays in flight
(factor ~ 8)

SS and WC tracking helps veto decays in flight

Using SS tracking to determine Z of the vertex helps to suppress decays-in-flight even further.

total factor ~ 30

$$\pi^+ \rightarrow e^+ \nu \text{ at PSI}$$

Precision Goal: 0.05%

$K \rightarrow e\nu$ & $K \rightarrow \mu\nu$ Selection Criteria

- Exactly one track
- Restricted decay vertex for reconstruction
- $K \rightarrow e\nu$ $E/P > 0.95$
- $K \rightarrow \mu\nu$ $E/P < 0.2$
- "Missing Mass" $M_X \approx 0$ defines $K^\pm \rightarrow l^\pm \nu$

$$|M_X|^2 = (E_K - E_l)^2 - (\mathbf{p}_K - \mathbf{p}_l)^2 < 0.015 \text{ GeV}^2$$

- $E_\gamma^{LKr} < 2 \text{ GeV}$ (Radiative Decay) ·

limited by calorimeter response.

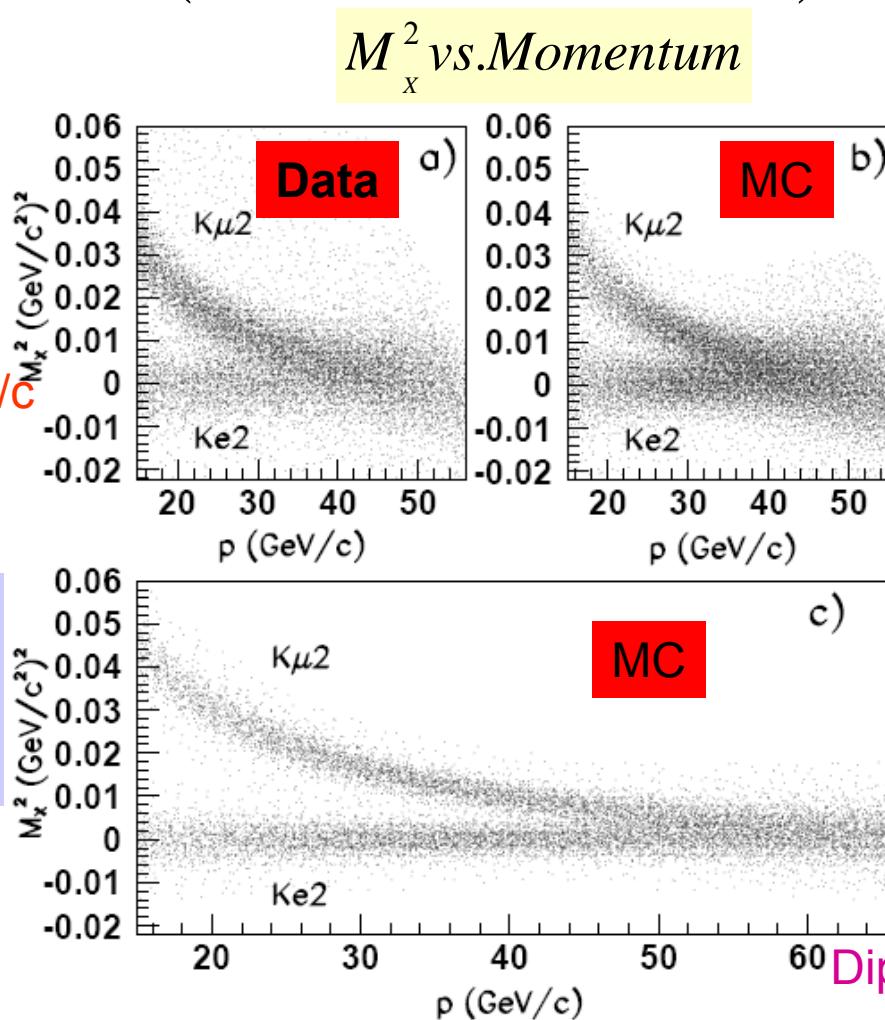

Missing Mass Technique

(μ reconstructed as e)

NA48 DATA 2004:
 K_{e2} candidates
 and a K _{μ 2} sample
 $P_K = 60 \text{ GeV}/c$
 Dipole Pt kick $120 \text{ MeV}/c$

Background:
 $K_{\mu 2}$ misidentified
 as K_{e2} for $P > 35 \text{ GeV}/c$.

2004 MC :
 Equal samples of
 K_{e2} and K _{μ 2}

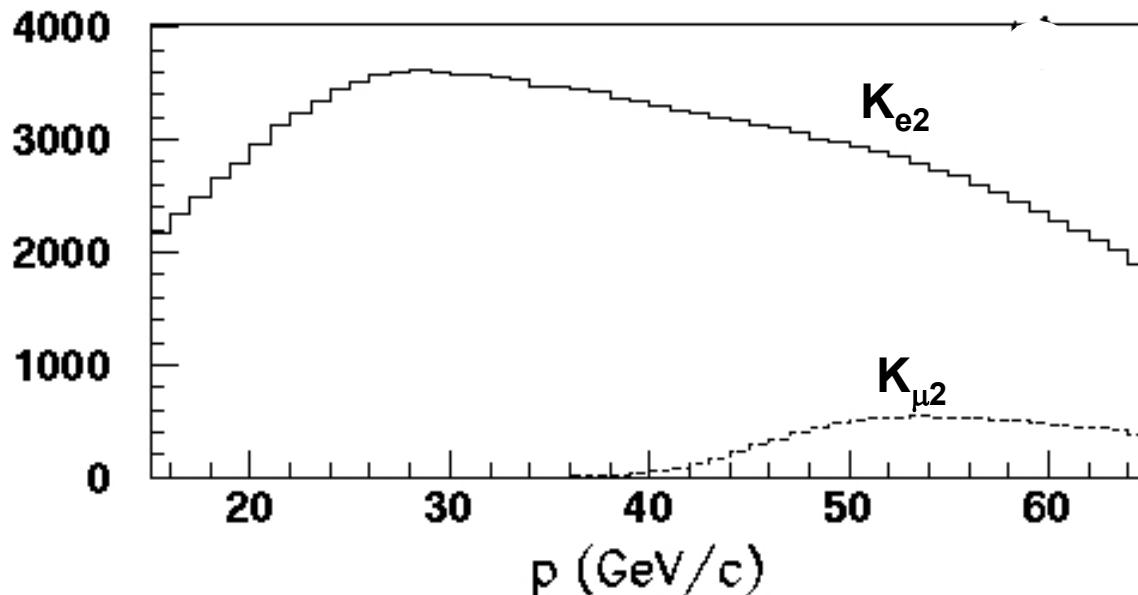

Some μ (5×10^{-6})
 misidentified as e
 for $p > 25 \text{ GeV}$

2007 MC :
 Equal samples of
 K_{e2} and K _{μ 2}
 $P_K = 75 \text{ GeV}/c$
 Dipole Pt kick: $263 \text{ MeV}/c$

Expected momentum distribution of electrons from K_{e2} decay and of fake electrons from $K_{\mu 2}$ for 150,000 K_{e2} decays

NA48/3 Monte
Carlo 2007

Decay vertex interval: $12m < z < 102 m$
($z=0$ corresponds to collimator downstream end)

For $p < 35$ GeV/c, 64,000 (43%) of events are background free.

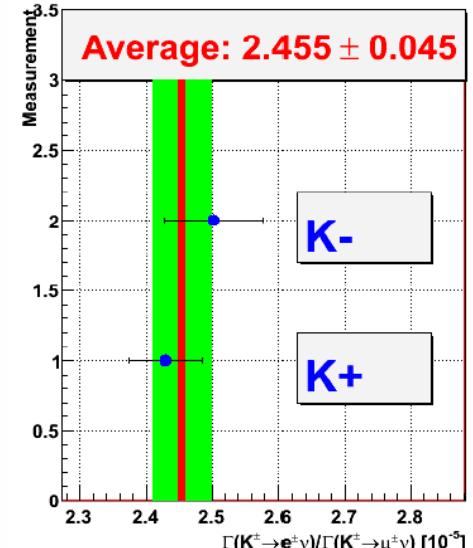

For $p > 35$ GeV, the fraction of muons from $K_{\mu 2}$ decay with $0.95 < E/p < 1.05$ will be measured by inserting a small lead plate in a region between the two hodoscope planes to give positive μ ID.

Errors

Source	Relative error	*
Ke2 sample statistics	1.85%	*
Kmu2 sample statistics	0.05%	
E/p correction for the electrons (E/p>0.95 cut)	0.18%	*

The Secrets of Rare Decay Experiments

“BC”

"BC"

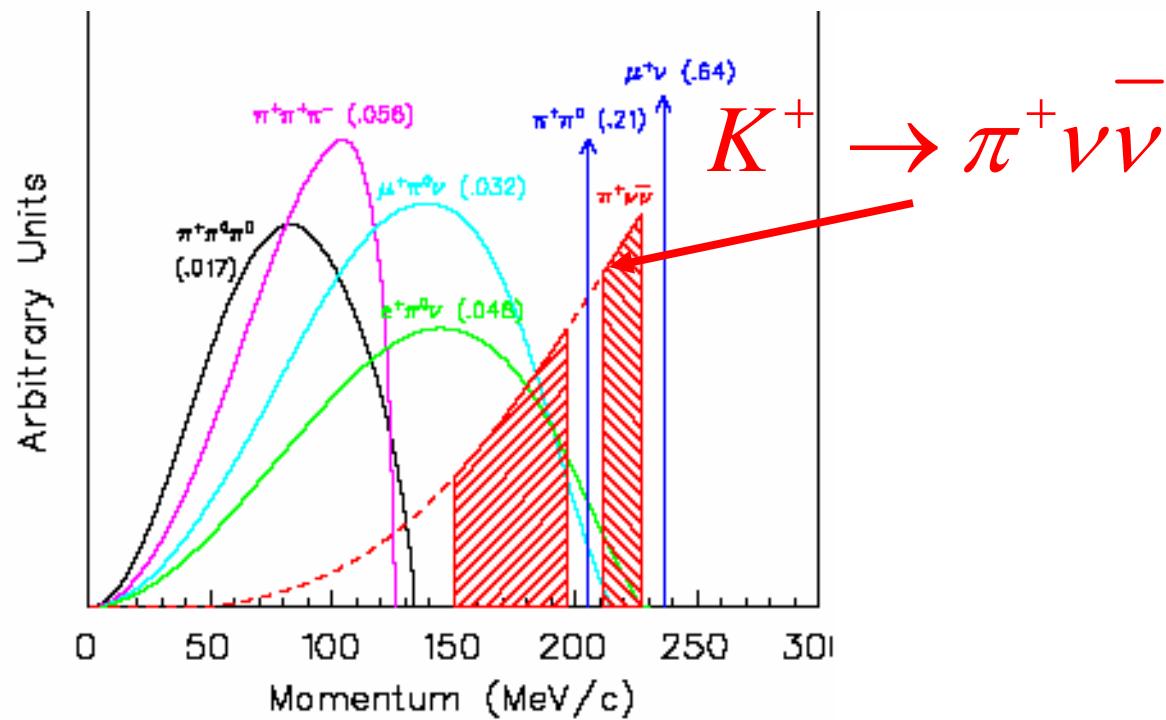

The Six Steps to Measuring $K \rightarrow \pi\nu\bar{\nu}$ Reactions

Step 1: Know the enemy.

K^+ Decay Modes $\tau_{K^+} = 12.4\text{ns}$

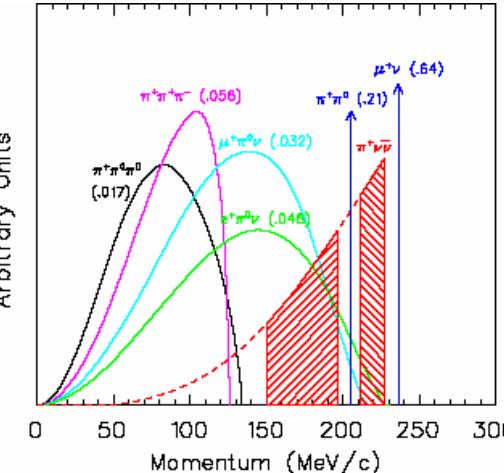

Decay Mode	Branching Ratio	Background Rejection
$K^+ \rightarrow \mu^+\nu$	63% (called $K_{\mu 2}$)	μ PID, Two-Body Kinematics
$K^+ \rightarrow \pi^+\pi^0$	21%	Photon Veto, Two-Body Kinematics
$K^+ \rightarrow \pi^+\pi^+\pi^-$	6%	Charged Particle Veto, Kinematics
$K^+ \rightarrow \pi^+\pi^0\pi^0$	2%	Photon Veto, Kinematics
$K^+ \rightarrow \pi^0\mu^+\nu$	3% (called $K_{\mu 3}^+$)	Photon Veto, μ PID
$K^+ \rightarrow \pi^0e^+\nu$	5% (called $K_{e 3}^+$)	Photon veto, E/p

Background processes exceed signal by $>10^{10}$

Approaching

$$K^+ \rightarrow \pi^+ \bar{\nu}\nu$$

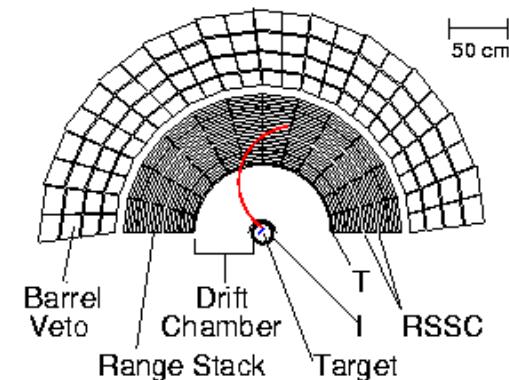

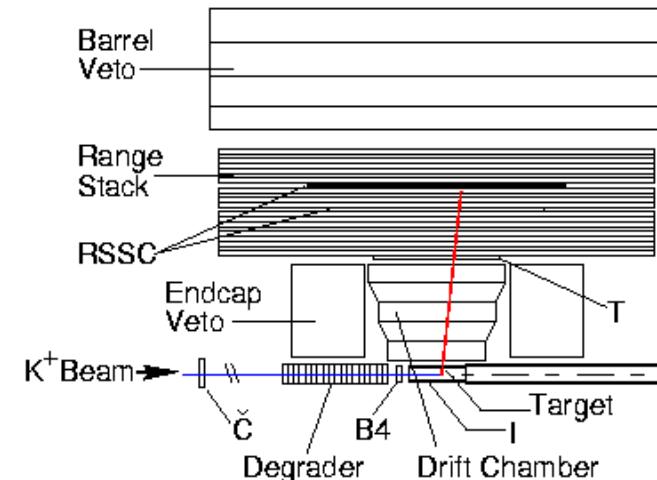

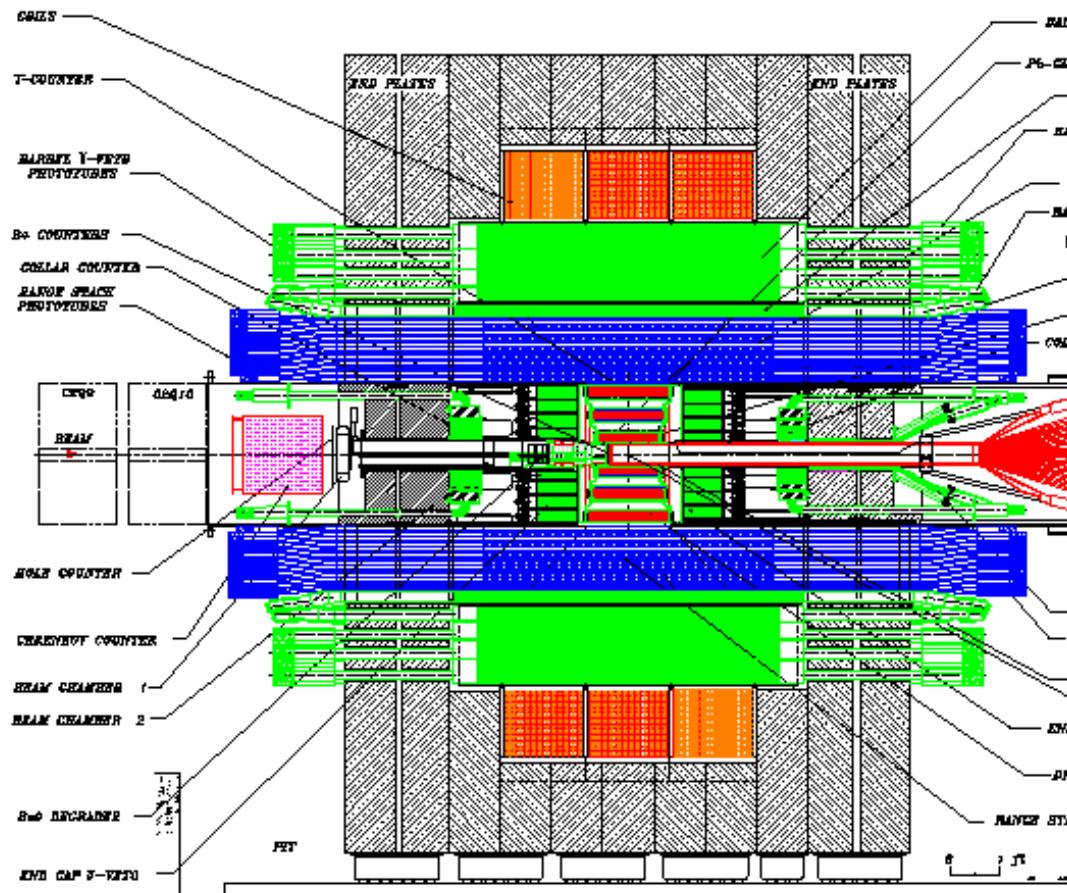

- Determine everything possible about the K^+ and π^+
 - * π^+/μ^+ particle ID better than 10^6 ($\pi^+ - \mu^+ - e^+$)
- Eliminate events with extra charged particles or *photons*
 - * π^0 inefficiency $< 10^{-6}$
- Suppress backgrounds well below the expected signal ($S/N \sim 10$)
 - * Predict backgrounds *from data*: dual independent cuts
 - * Use “Blind analysis” techniques
 - * Test predictions with “outside-the-box” measurements
- Evaluate candidate events with Signal/Noise function

Step 2: Create a giant filter

BNL E949

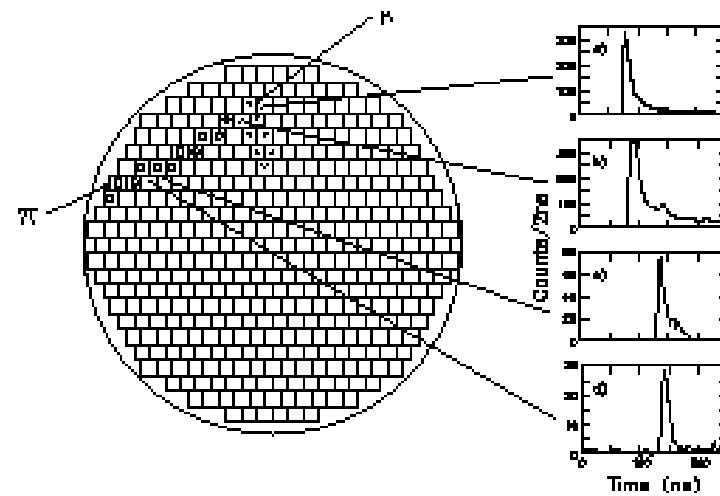

Measurement of

$$K^+ \rightarrow \pi^+ \nu \bar{\nu}$$

Special Instruments Required: 500 MHz Transient Digitizers

$K \rightarrow \pi$

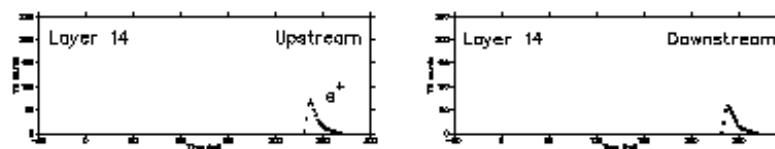

K stop

$K \rightarrow \pi$

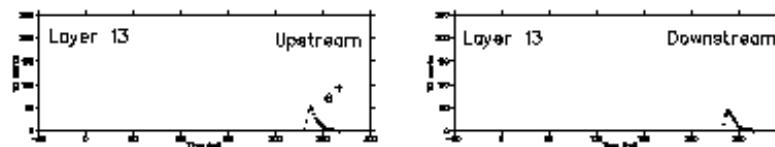

π

ν

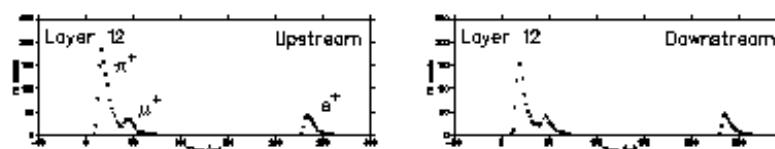

$\pi \rightarrow \mu \rightarrow e$

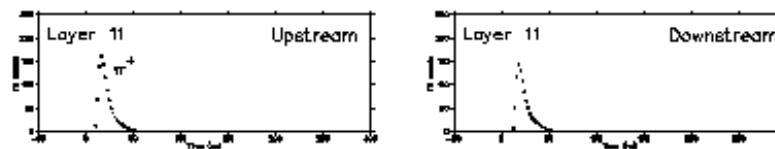

$e \uparrow$

$e \uparrow$

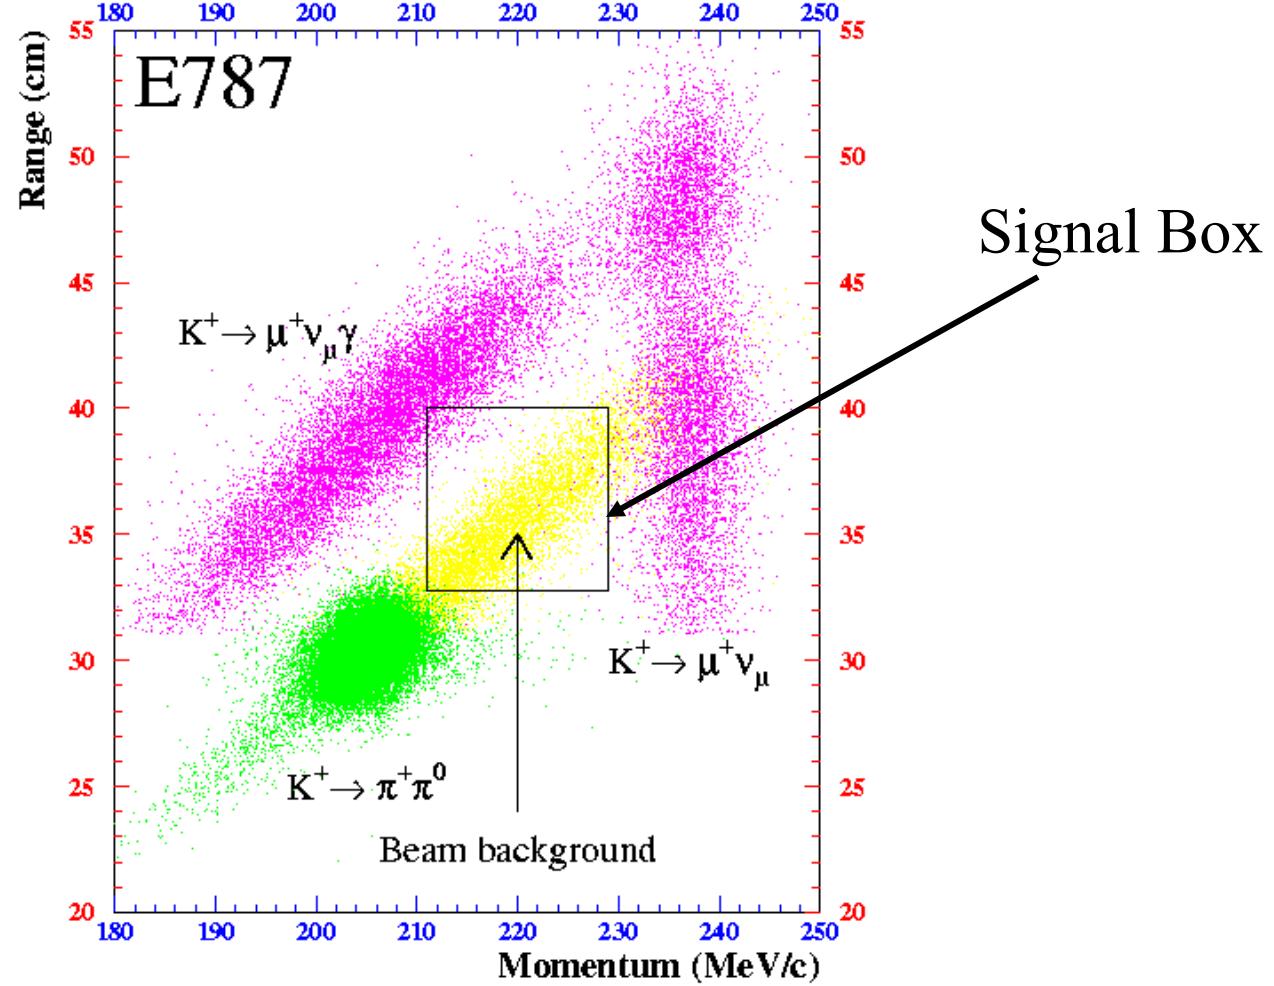

$\pi \rightarrow \mu / \mu \rightarrow e$

π enters \uparrow

Step 3: Demolish the Backgrounds

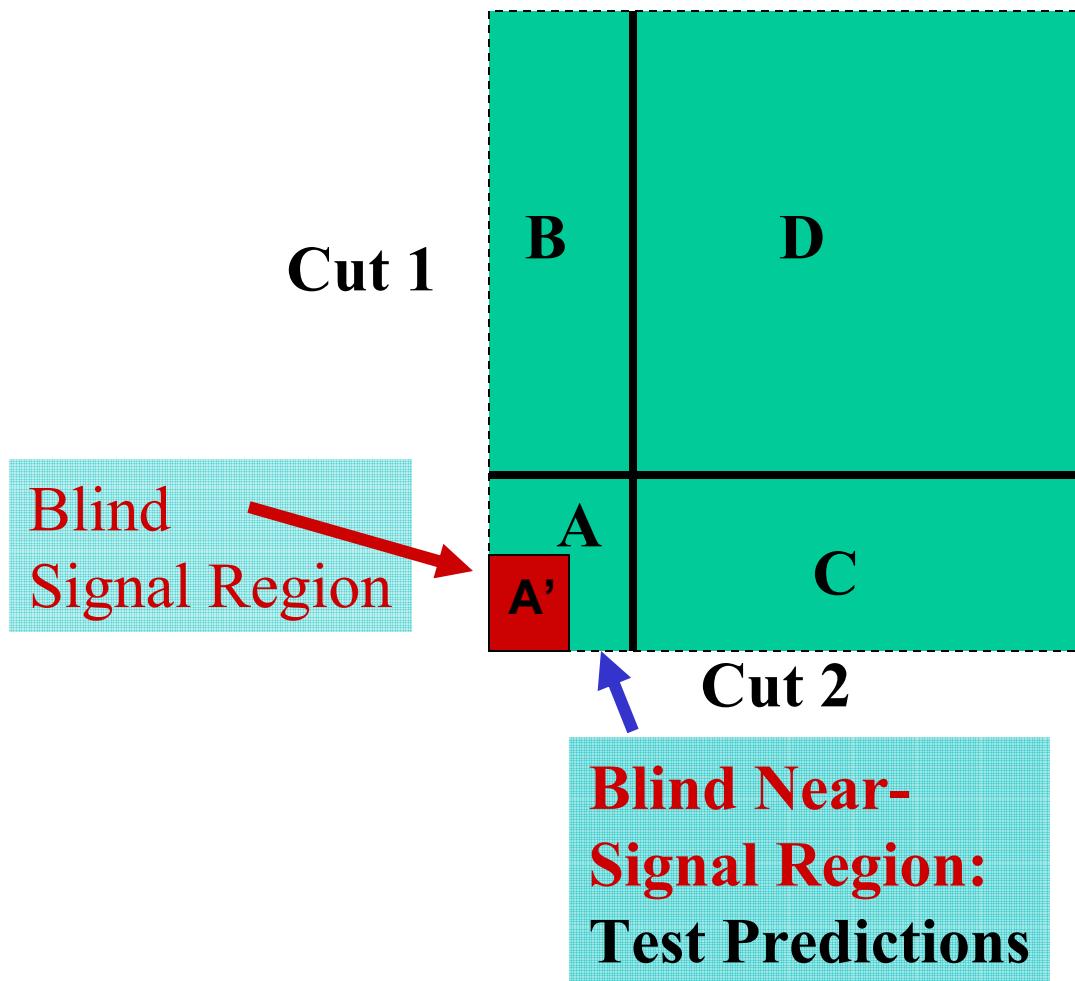

Background Processes: Range vs. Momentum

Estimating Backgrounds

Dual-Cut BLIND Analysis Method

Cut 1 vs Cut 2

If Cuts 1 and 2 are uncorrelated:
 $A/B=C/D$
Background in A:
 $A=B \quad C/D$

Use a subset (e.g. 1/3) of the data to finalize cuts which are then applied to the remainder of the data. Background estimates are also subject to blind analysis.

$K^+ \rightarrow \pi^+ \pi^0$ Background Suppression

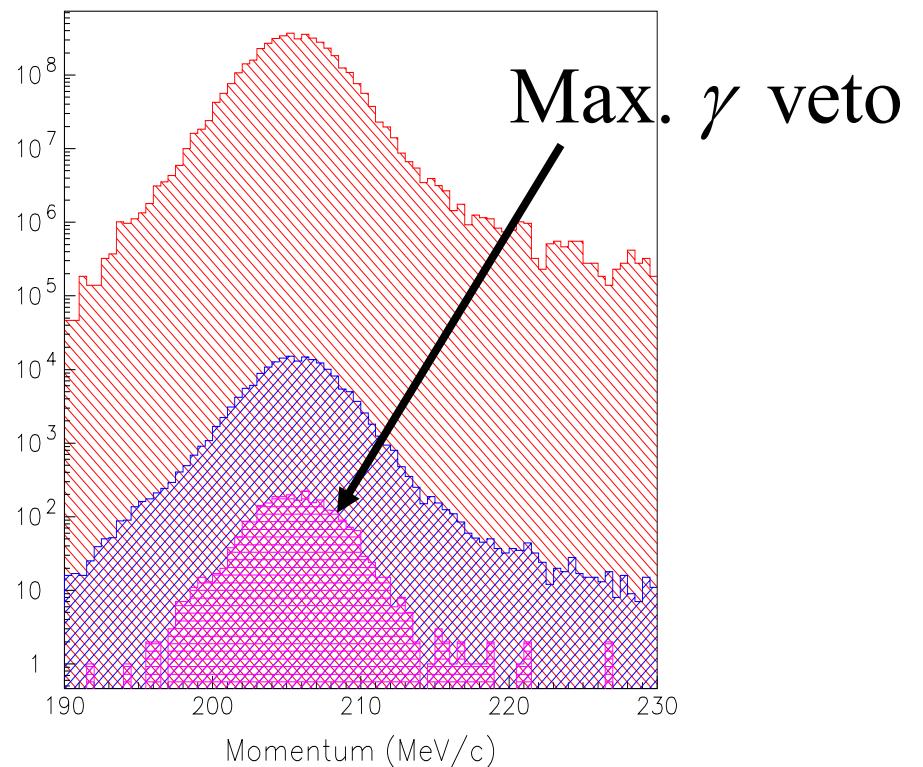

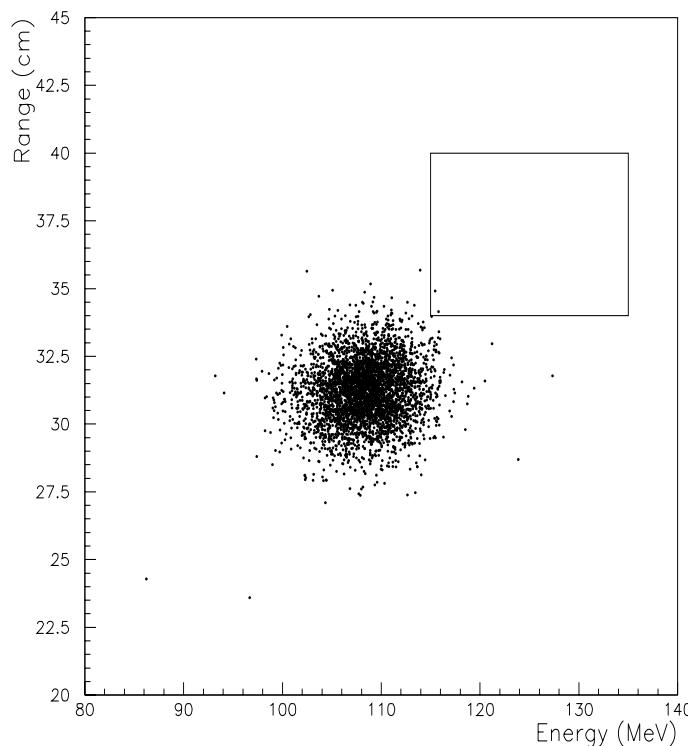

Dual cuts: γ Veto and Kinematics (P,R,E...)

γ Veto Reversed

Range vs. Energy

γ Veto Applied

Momentum

Important step: Check for correlations.

Background Suppression: E949 Improved Photon (π^0) Detection Efficiency

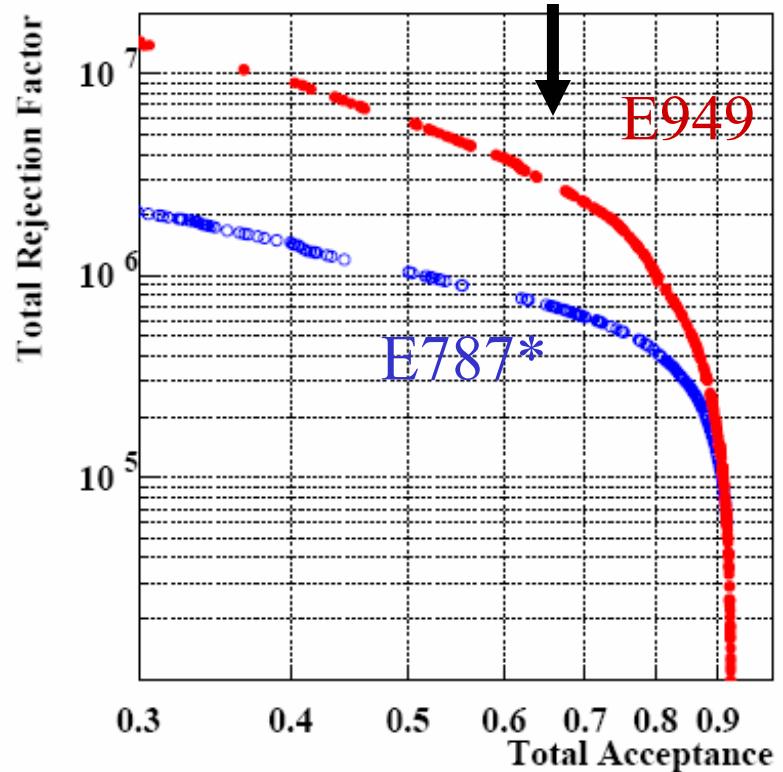

Photon Detection Efficiency limited by

- Photonuclear interactions (" $\gamma \rightarrow n$ ")
- Sampling Fluctuations
- Punch-through

π^0 Rejection: $>10^6$
(for $K^+ \rightarrow \pi^+ \pi^0$ background)

Twice the rejection
of π^0 backgrounds
at comparable acceptance
for $K^+ \rightarrow \pi^+ \nu\bar{\nu}$.

Rejection vs. Acceptance

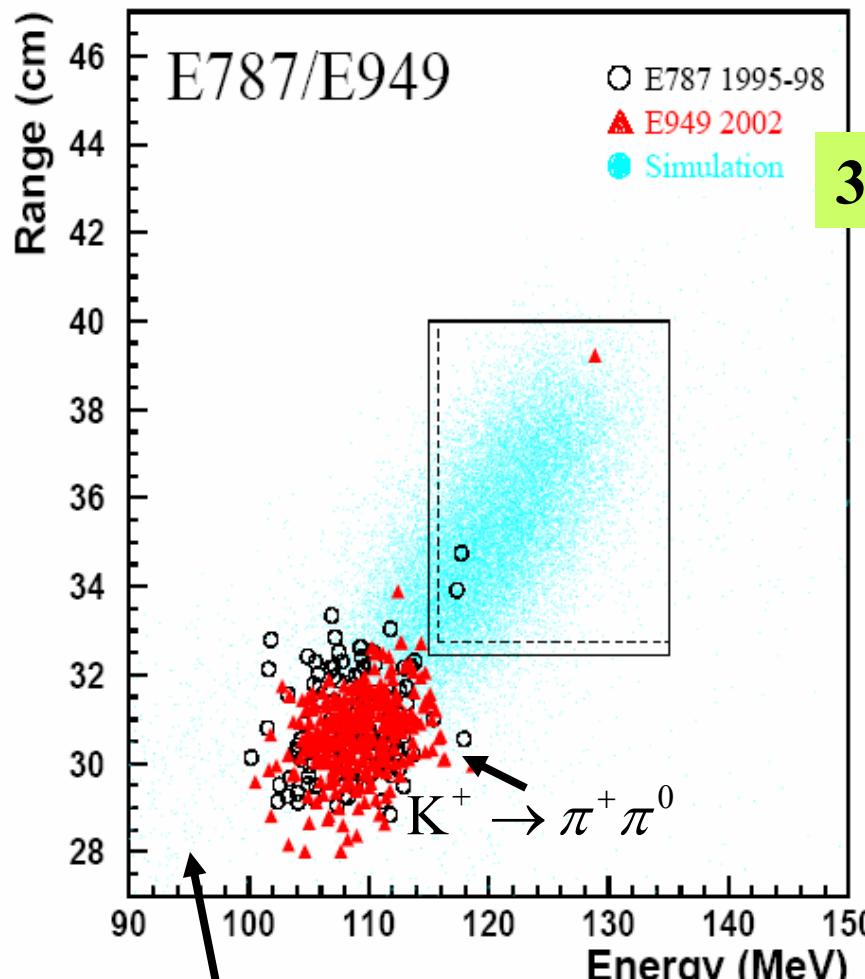

* E787 was a previous version of E949.

*Step 4:*Open the Box

Combined E787/E949 Branching Ratio

$$B(K^+ \rightarrow \pi^+ \bar{\nu} \bar{\nu}) = 1.47 \pm^{1.30}_{0.89} \times 10^{-10}$$

$$B_{\text{SM}}(K^+ \rightarrow \pi^+ \bar{\nu} \bar{\nu}) = 7.8 \pm 1.2 \times 10^{-11}$$

3 events observed—consistent with SM

	E787	E949
N_K	5.9×10^{12}	1.8×10^{12}
Total Acceptance	0.0020 ± 0.0002	0.0022 ± 0.0002
Total Background	0.14 ± 0.05	0.30 ± 0.03
Candidate	1995A	1998C
S/b	50	7
W	0.98	0.88
Background Prob.	0.006	0.02
		0.07

Low energy phase space data under analysis.

Step 5: Get lots of events!

CERN Proposal P-326 : $K^+ \rightarrow \pi^+ \nu \bar{\nu}$

Goal: >80 events for $B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) = 10^{-10}$

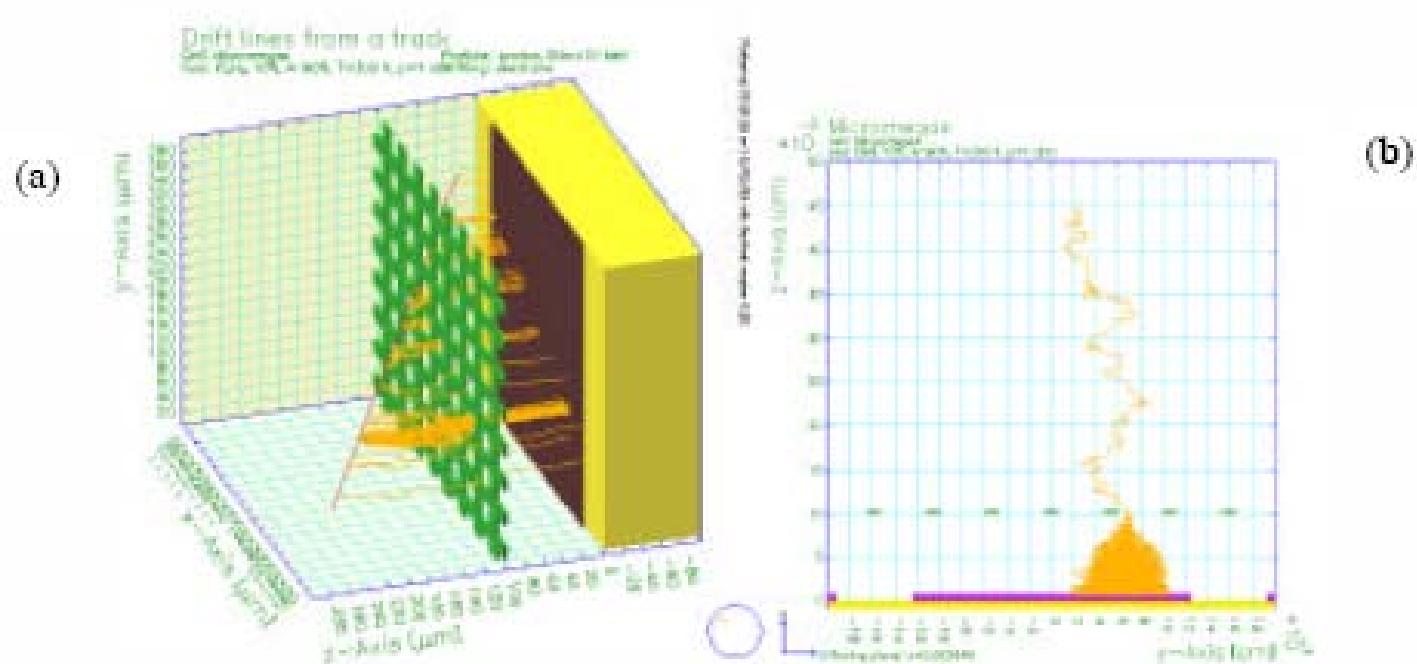

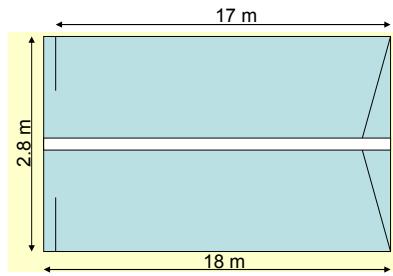

Resolutions: $\frac{\Delta P_K}{P_K} \sim 0.3\%$, $\frac{\Delta P_\pi}{P_\pi} \sim 1\%$, $\Delta \theta_{K\pi} \sim 60 \mu\text{rad}$

P-326 Detector Challenges

Detector/System	
CEDAR	Differential Cerenkov Detector – tag K
Gigatracker (SPIBES, FTPC)	Si micro-pixels, TPC- measure P_K @ 1 GHz
Straws tracker in vacuum	Charged particle detectors
Large Angle Veto	Photon Veto detectors (9-50 mrad) : Pb/Scint. WLS fiber readout
SAC/IRC	Small, intermediate angle P.V. (<1 mrad): shashlyk Pb, scintillating fiber towers./PbWO4
MAMUD	Muon particle i.d. (range); Magnetized Fe/Scint. Hadron calorimeter.
RICH	Ring Imaging Cerenkov Detector – pi/mu i.d.
LKr Consolidation	Calorimeter – P.V. (1-9 mrad)

Gigatracker Micromegas Tracking/TPC

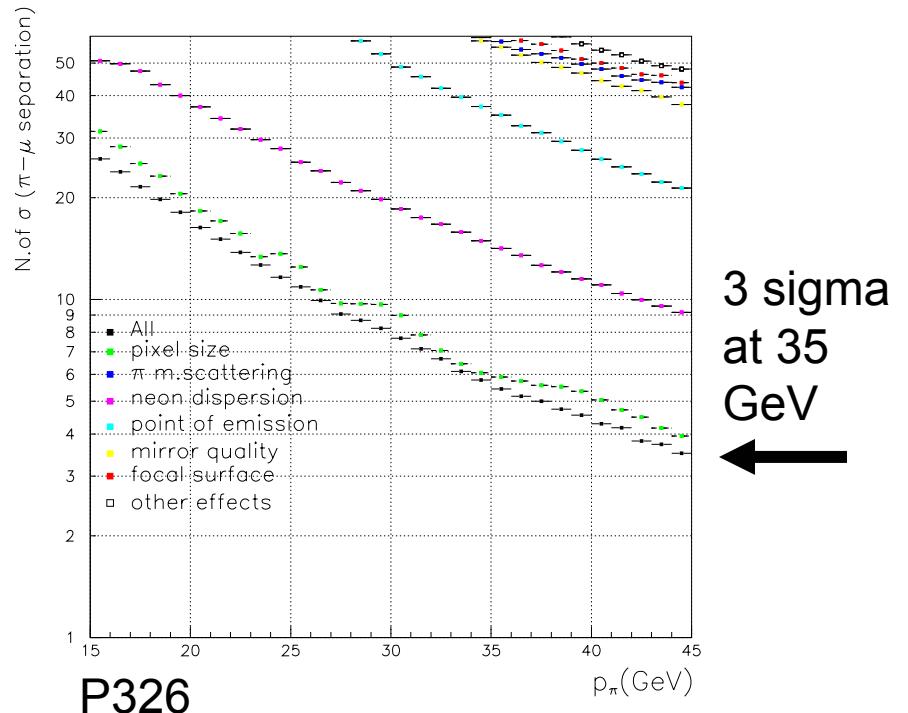

RICH counter

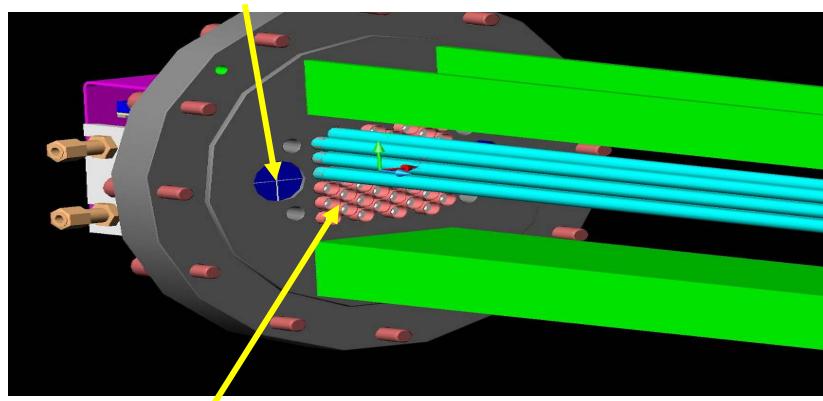

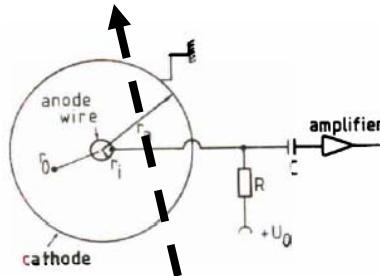

- **RICH Specifications for $K^+ \rightarrow \mu^+\nu$ rejection:**
 - Separate $\pi-\mu$ at $\geq 3\sigma$ from 15 to 35 GeV
 - Time resolution: ≤ 100 ps
- Radiator: **Neon**
- 1 atm, $(n-1)=67 \times 10^{-6}$
- π threshold = 12 GeV
- (15 GeV for full eff.)
- Length: ~ 18 m (**5.6% X_0**)
- Focal: 17 m 2 mirrors (eff.)
- **~ 2000 PMTs**
- Hamamatsu 7400-U03
- Dispersion: 1.6×10^{-6} (convoluted with PMT response)
- Pixel size: **18 mm**
- Single Anode PMTs
- PMTs matrix on the focal plane with compact hex packing

Sigma $\pi-\mu$ separation vs.
Momentum

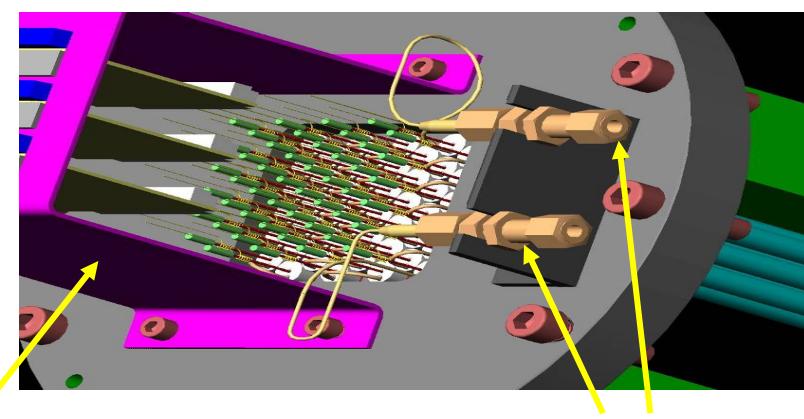

Straw Tracking in Vacuum

Gas proportional chamber;
wires (anode) strung in
thin “soda straw”
cathodes.

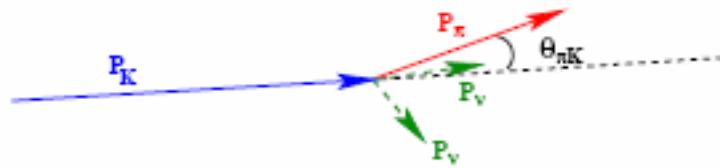

48 holes for straws:
8 layer x 6 straws

**R/O electronics
box**

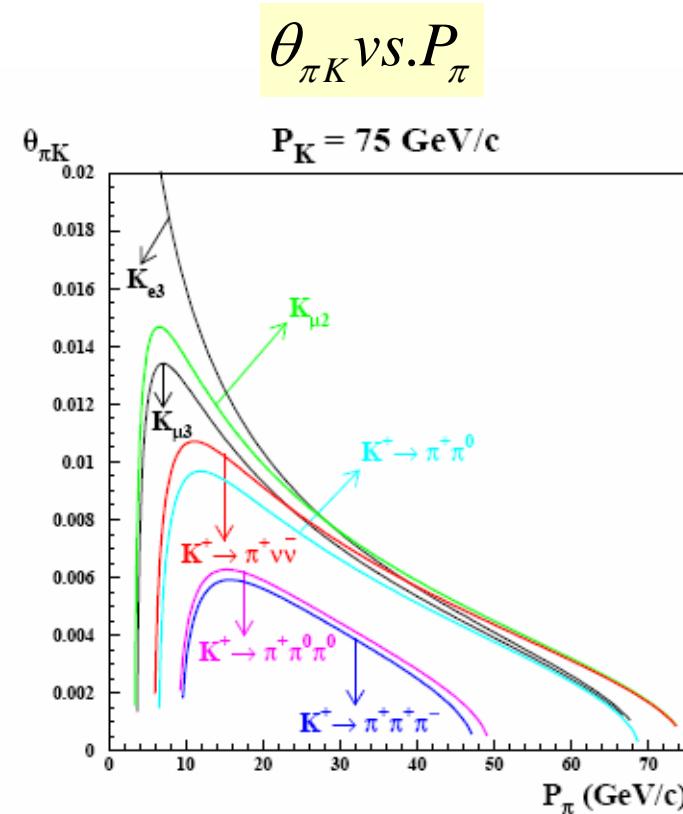

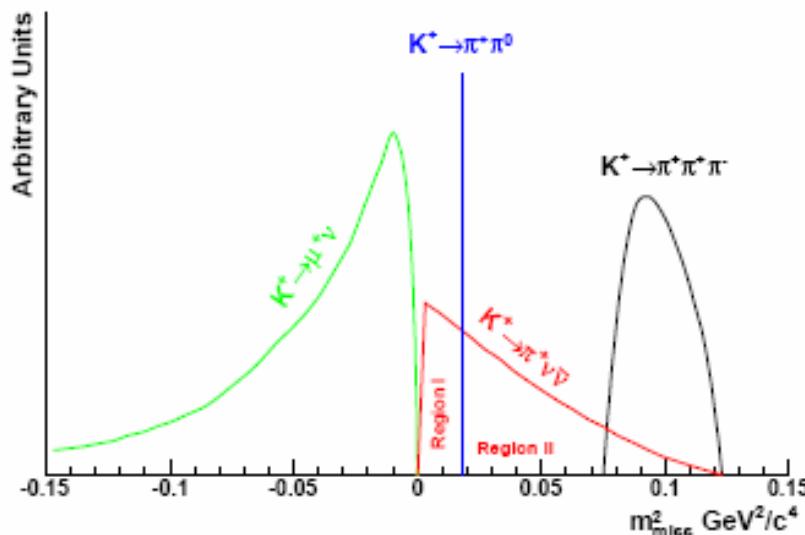

Gas connectors

$K^+ \rightarrow \pi^+ \nu \bar{\nu}$ Kinematics and Backgrounds at 75 GeV

$$m_{miss}^2 \simeq m_K^2 \left(1 - \frac{|P_\pi|}{|P_K|}\right) + m_\pi^2 \left(1 - \frac{|P_K|}{|P_\pi|}\right) - |P_K||.$$

Missing Mass $K^+ \rightarrow \pi^+ (M_{miss})$

No Missing Mass Constraints:

	$K^+ \rightarrow e^+ \pi^0 \nu$	$K^+ \rightarrow \mu^+ \nu \gamma$	$K^+ \rightarrow \pi^+ \pi^0 \gamma$
BR	4.87×10^{-2}	5.50×10^{-3}	2.75×10^{-4}
Acceptance	13.4%	15.3%	17.9%
η_μ	—	10^{-5}	—
η_{π^0}	5×10^{-8}	—	5×10^{-8}
η_γ	—	2×10^{-4}	10^{-3}
$\eta_{\pi e}$	10^{-3}	—	—
S/B	30	5	4000

P326 Proposal (2006)

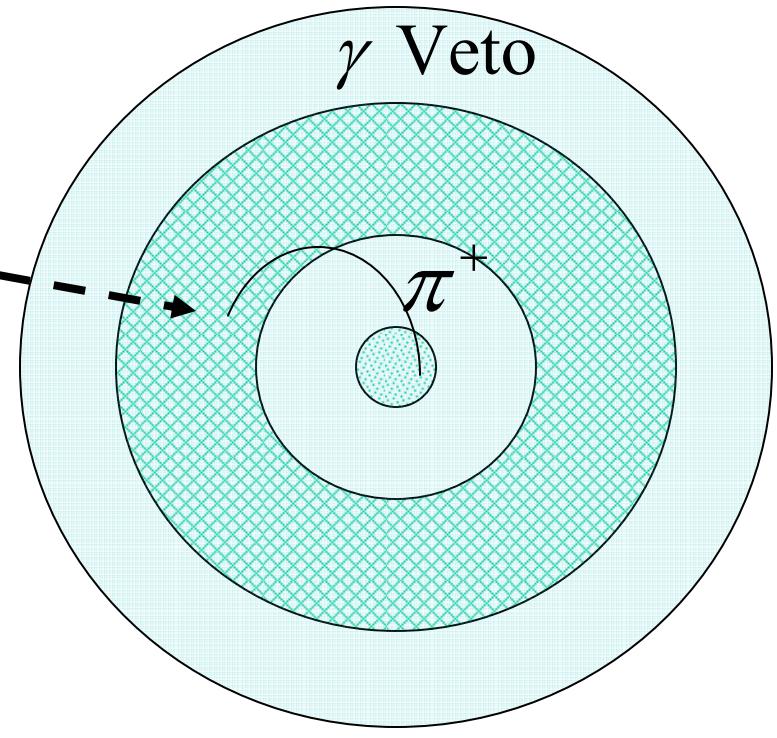

New Approaches to $K^+ \rightarrow \pi^+ \nu\bar{\nu}$:

High Field Version of E787/E949

Compact High Rate Detector

- Sci-Fi target and range stack
for high rate $\pi \rightarrow \mu \rightarrow e$
- Improved momentum measurement
suppresses $K^+ \rightarrow \pi^+ \pi^0, \rightarrow \mu^+ \nu$
- Improved crystal photon veto detectors

Possible J-PARC experiment.
50-100 events at S/N=5

Step 6: Tackle Something even harder:

$K_L^0 \rightarrow \pi^0 \bar{\nu}\bar{\nu}$ Experiments

Theory: $(3.0 \pm 0.6) \times 10^{-11}$

Limit from $K^+ \rightarrow \pi^+ \bar{\nu}\bar{\nu}$ via isospin: $< 1.4 \times 10^{-9}$ • [Grossman, Nir]

• KTEV (FNAL) result: $B(K_L^0 \rightarrow \pi^0 \bar{\nu}\bar{\nu}) < 5.9 \times 10^{-7}$ (90% CL)

• KEK E391a: $B(K_L^0 \rightarrow \pi^0 \bar{\nu}\bar{\nu}) < 2.1 \times 10^{-7}$ (90% CL)

• JPARC Proposal:

Phase 1: Single event Sensitivity 10^{-10}

• KOPIO Concept: $< 10^{-12}$

The Challenges

- $B(K_L \rightarrow \pi^0 \bar{\nu} \nu) \sim 3 \times 10^{-11}$;
need huge flux of K's -> high rates
- Weak Kinematic signature ($\pi^0 + 2$ particles missing)
- Backgrounds with π^0 up to 10^{10} times larger
- Veto inefficiency on extra particles must be $\leq 10^{-4}$
- Neutrons dominate the beam
 - make π^0 off residual gas – require high vacuum
 - halo must be very small
 - hermeticity requires photon veto in the beam
- Need convincing measurement of background

$K_L^0 \rightarrow \pi^0 \nu \bar{\nu}$ Measurement

Background suppression factor needed: 10^{10}

Primary Backgrounds

Mode	Branching Ratio
$K_L^0 \rightarrow \pi^0 \pi^0$	0.93×10^{-3}
$K_L^0 \rightarrow \pi^- e^+ \nu \gamma$	0.36×10^{-2}
$K_L^0 \rightarrow \pi^+ \pi^- \pi^0$	0.1255
$K_L^0 \rightarrow \pi^0 \pi^0 \pi^0$	0.2105
Others	

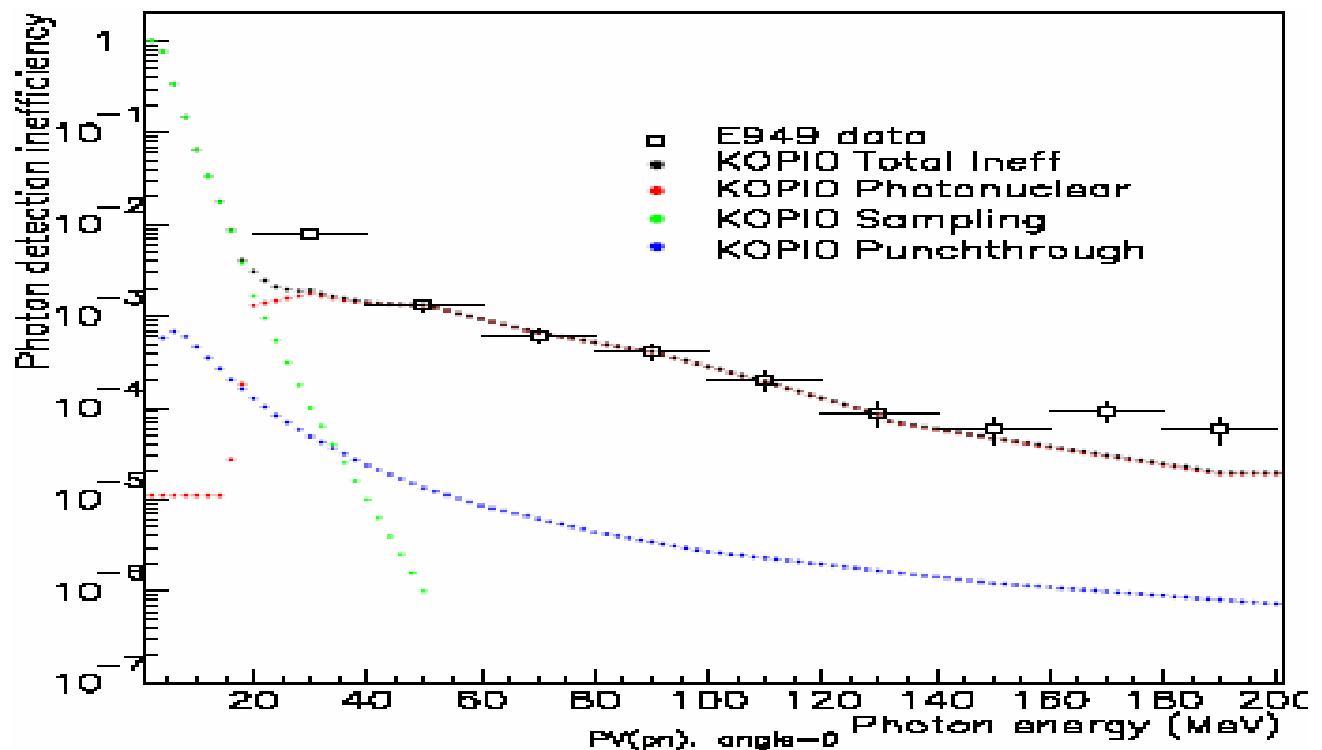

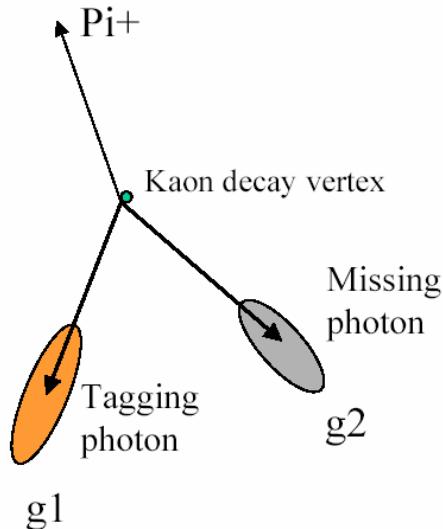

Photon Veto Efficiency Estimates and Simulations based on improved E949 Measurements supplemented by FLUKA calculations

Photon Detection Efficiency limited by

- Photonuclear interactions (" $\gamma \rightarrow n$ ")
- Sampling Fluctuations
- Punch-through

1 MeV Visible Energy Threshold

KP2 Decay

Photon Veto Inefficiencies Assumed for JPARC $K_L^0 \rightarrow \pi\nu\nu$

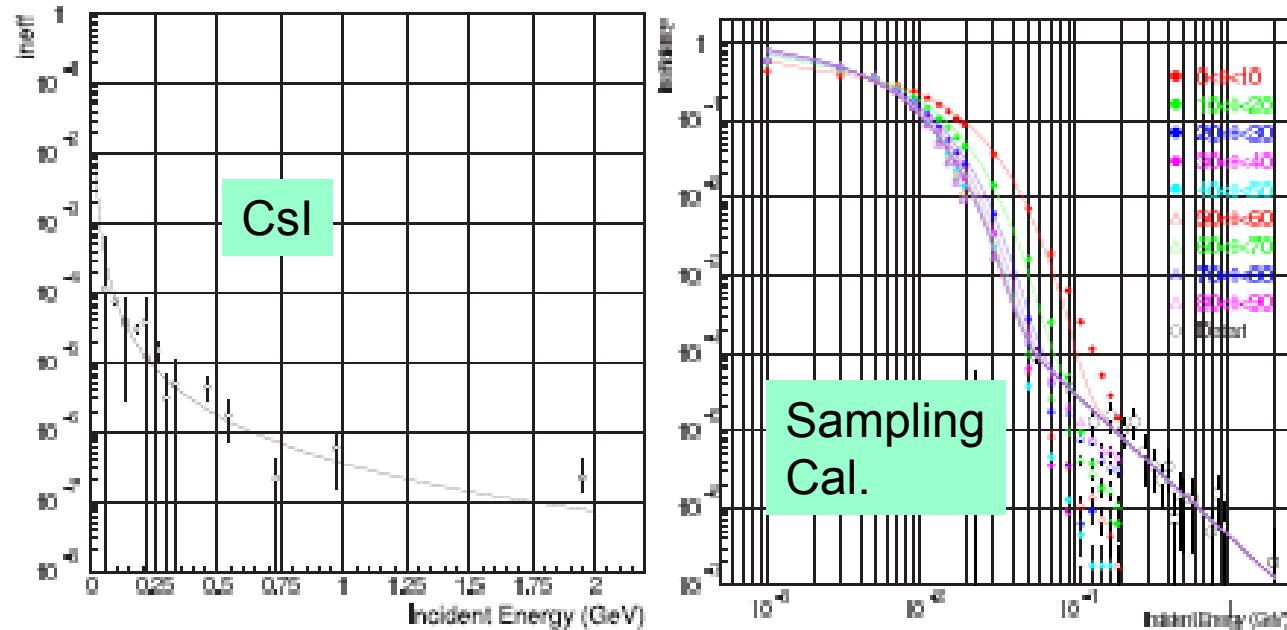

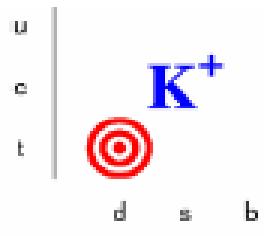

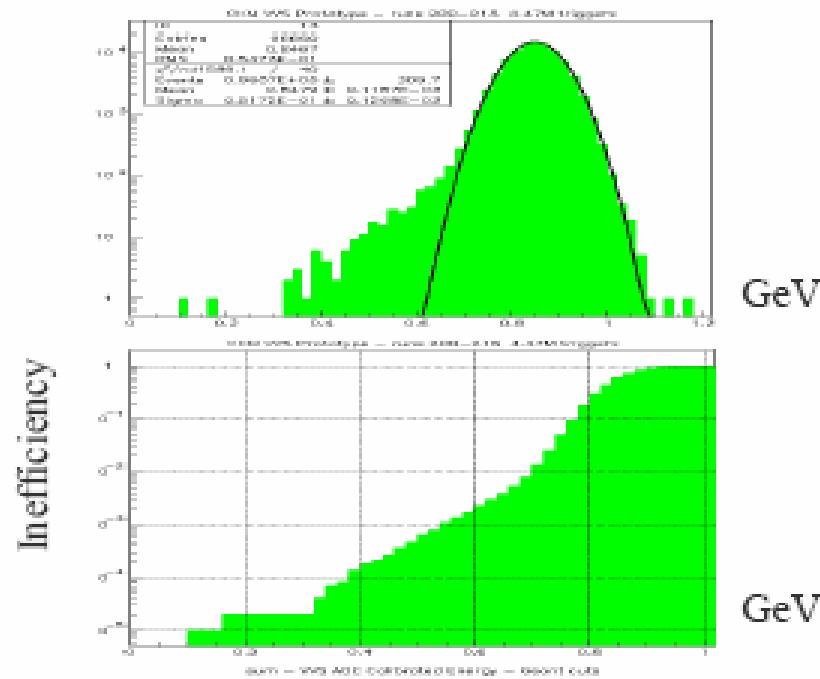

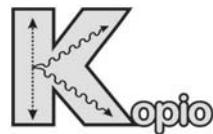

Figure 56: Photon detection inefficiencies for CsI crystals (Left) and a sampling calorimeter (Right) as a function of incident photon energy. The open black circles are experimental data for photonuclear interactions. Monte Carlo results for the inefficiencies due to punch-through and sampling fluctuations are shown in the Right figures as colored points. Different colors indicate different incident angles on the detector. The solid curves are the model inefficiency functions obtained by fitting the data and Monte Carlo results.

Photon Veto Inefficiency and Technology

- 0.3% VVS Prototype built
- Tested at JLAB in an e^- beam
- Achieved $<1 \times 10^{-5}$ (3×10^{-6}) veto inefficiency at 1 GeV (required 3×10^{-5})

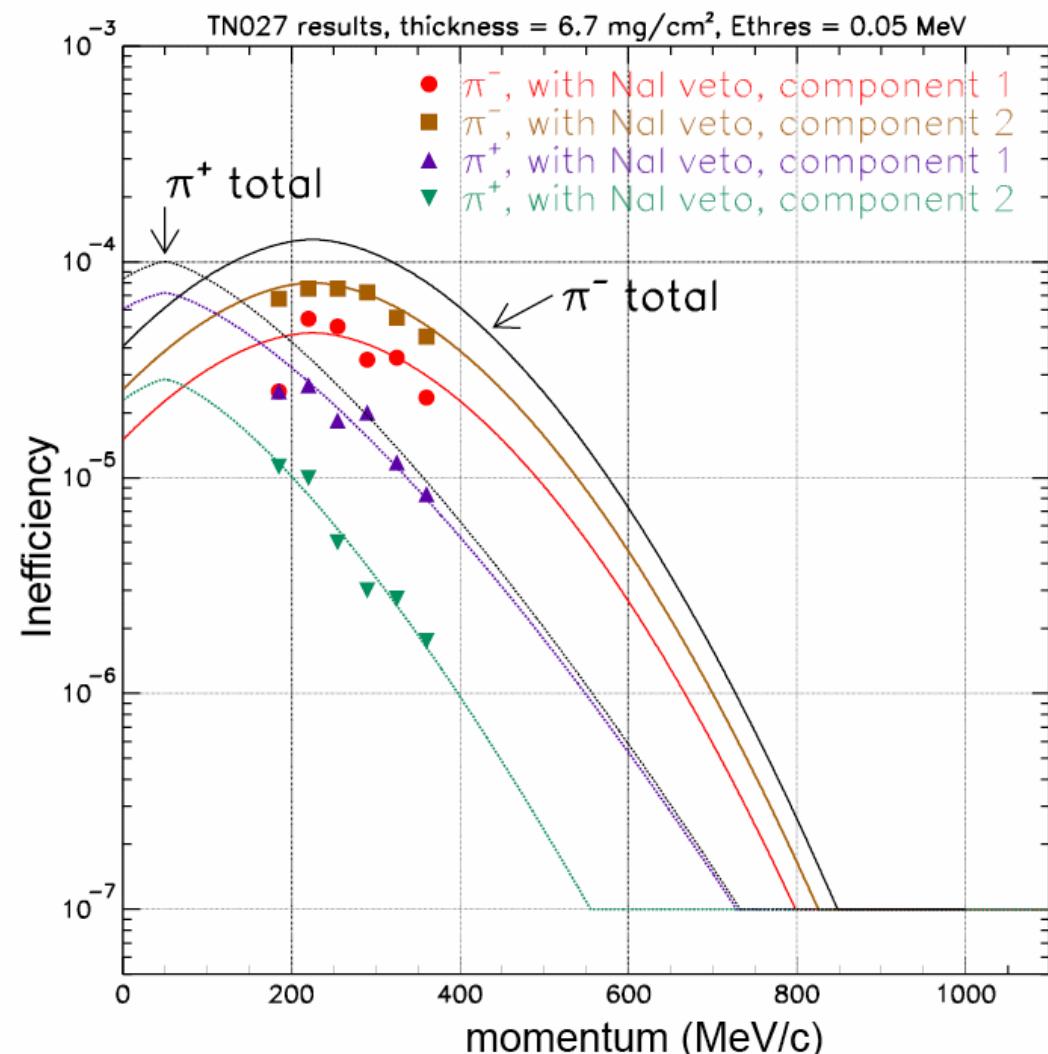

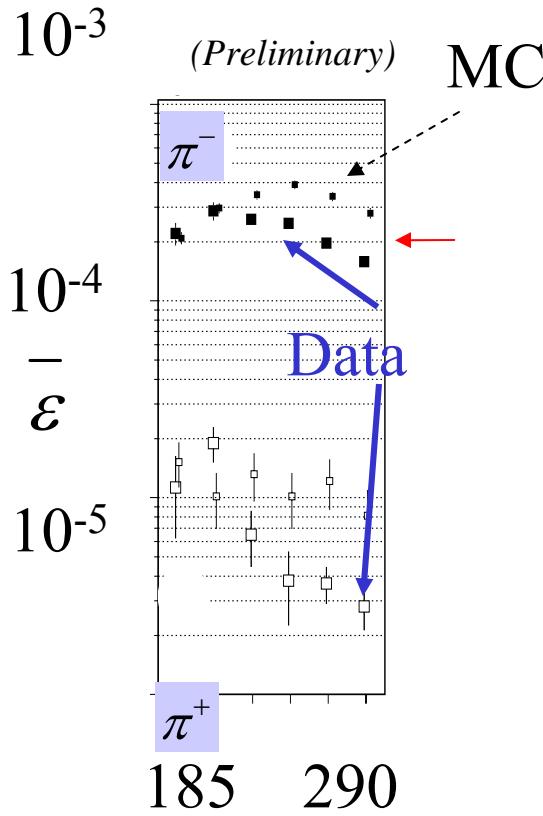

Charged Particle Vetoing

Example Background: $K_L^0 \rightarrow \pi^- e^+ \nu \gamma$

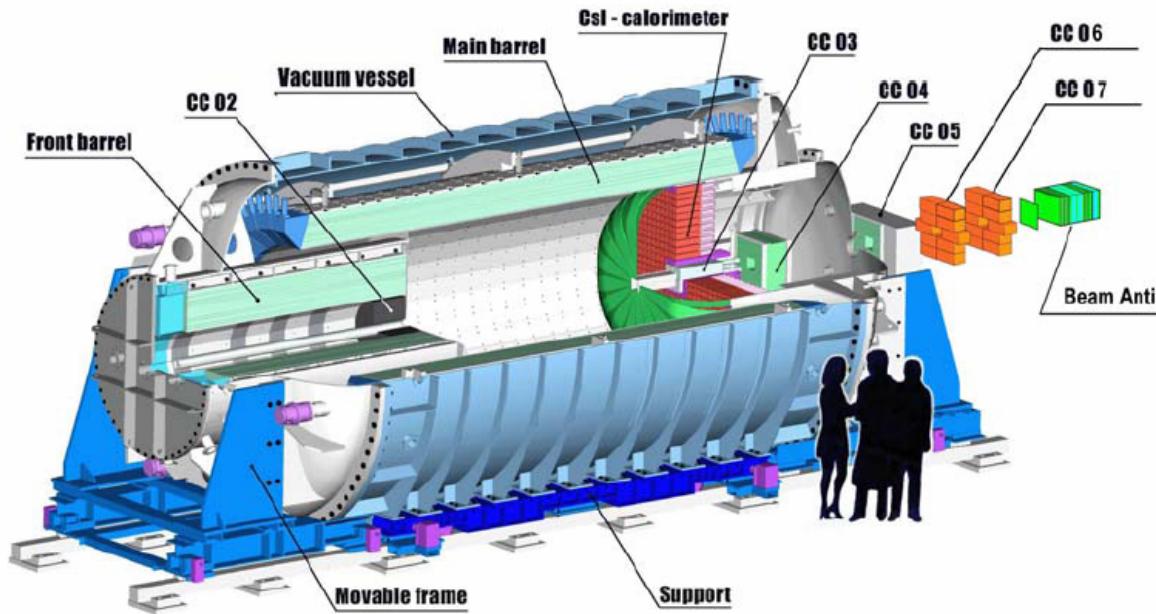

Plastic Scintillator –

backed up by γ vetoes!

PSI Measurement

KEK PS E391a >>> JPARC with KTEV CsI

Features:

- * Pencil Beam
- * High acceptance
- * High P_T selection

- * Pilot Project for JHF
- * Test reliance on extreme photon veto efficiency

2006 Result: $B(K_L^0 \rightarrow \pi^0 \bar{\nu}\nu) < 2.1 \times 10^{-7}$ (90% CL)

KEK PS E391a >>> JPARC

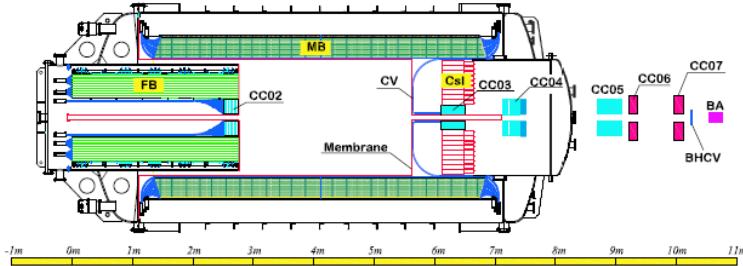

FIG. 1: Cross section of the E391a detector. K_L^0 's enter from the left side.

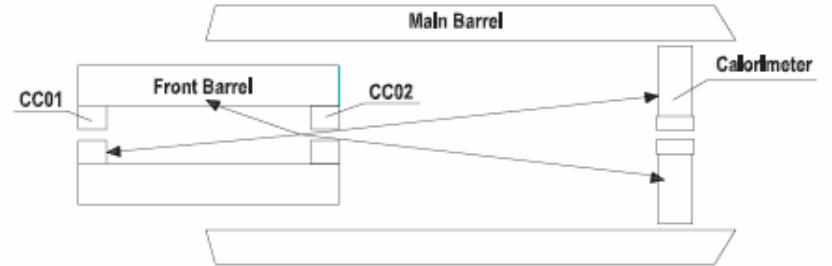

Figure 26: Schematic view of the role of the upstream decay chamber.

$$\text{S.E.S.} = 1/(N_K \times \text{decay probability} \times \text{acceptance}) = 4.0 \times 10^{-12}$$

With a Standard Model prediction of $\mathcal{B}(K_L \rightarrow \pi^0 \nu \bar{\nu}) = 2.8 \times 10^{-11}$, we expect to observe 7.0 events in Step 1. If the acceptance loss is 50% as we estimated, the S.E.S. is 8.0×10^{-12} and 3.5 Standard Model events are expected.

Calorimetry and Photon Veto

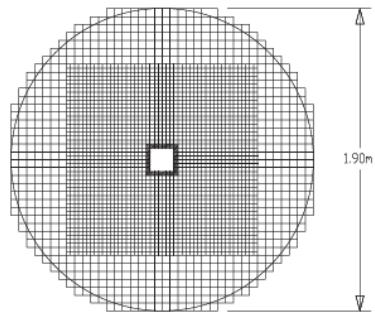

Figure 15: Layout of the Calorimeter for the J-PARC experiment with the KTeV CsI crystals. The $2.5 \times 2.5 \times 50\text{-cm}^3$ crystals are used for the inner region, and $5.0 \times 5.0 \times 50\text{-cm}^3$ crystals are used for the outer region.

Transverse Momentum P_T vs. Vertex Position (Z)

$$K_L^0 \rightarrow \pi^0 \nu \bar{\nu}$$

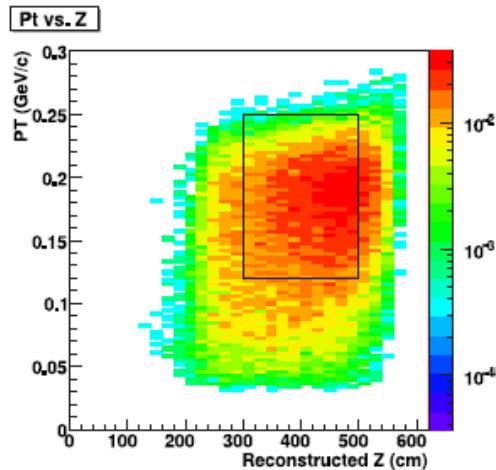

Figure 33: Distribution of P_T vs. the reconstructed z position for the $K_L \rightarrow \pi^0 \nu \bar{\nu}$ signal events. The box shows the signal region.

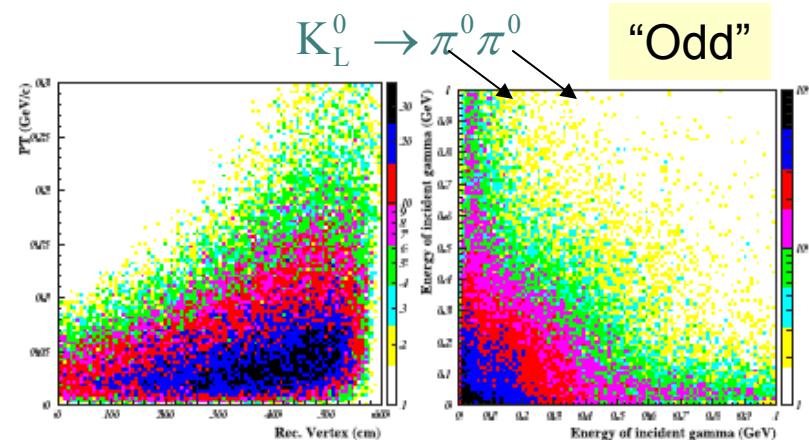

Figure 35: Left: reconstructed vertex and P_T distribution for odd-pairing $K_L \rightarrow \pi^0 \pi^0$ background. The reconstructed vertex is not correct which make the P_T lower than the signal box. Right: Energy distribution of photons that enter the veto counters. Even though many events have low energies for both of the photons, the events are rejected through the high- P_T selection. As a result, the photons needed to be rejected by the veto counters have distributions similar to those for even pairing.

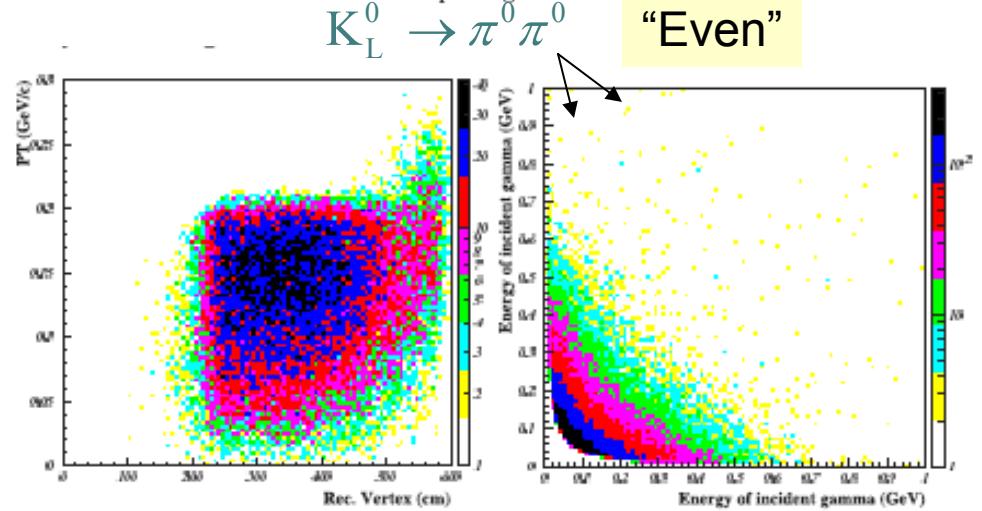

Figure 34: Left: reconstructed vertex and P_T distribution for even pairing $K_L \rightarrow \pi^0 \pi^0$ background. It has a distribution similar to that of the $K_L \rightarrow \pi^0 \nu \bar{\nu}$ decay. Right: Energy distribution of gammas that enter the veto counters. At least one photon has sufficiently high energy to trigger the counter with a high detection efficiency.

KEK PS E391a >>> JPARC with KTEV CsI

Estimates: Signal (SM) 7

Background 5 (dominated by $K_L^0 \rightarrow \pi^0 \pi^0$)

Table 7: The estimated number of background events for Step 1. The single event sensitivity is 4.0×10^{-12} , with which 7.0 standard model events are expected. With a 50% of acceptance loss, both the number of expected signal events and background events would be scaled accordingly.

Background source	#Background events
Other K_L decays	
$K_L \rightarrow \pi^0 \pi^0$	3.65
$K_L \rightarrow \pi^+ \pi^- \pi^0$	0.93
$K_L \rightarrow \pi^- e^+ \nu$	0.01
$K_L \rightarrow \gamma\gamma$	negligible
$K_L \rightarrow \pi^0 \pi^0 \pi^0$	negligible
Neutron Interaction	
With Residual gas	0.07
At the CC02	0.26
At the C.V.	negligible
Accidental Coincidence	0.20

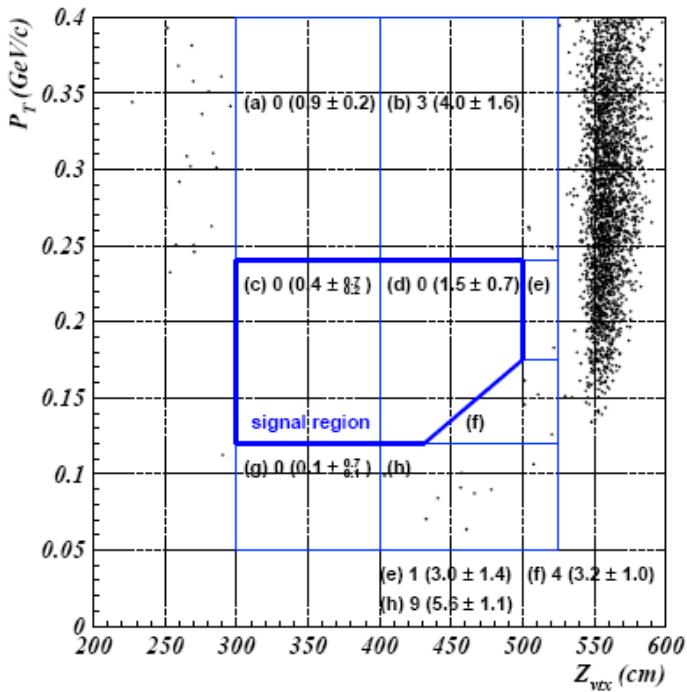

FIG. 3: Z_{vtx} versus P_T with all the event selection cuts. The number of observed (total expected background) events are shown. The expected number of background events was consistent with the observed number of events for all the regions.

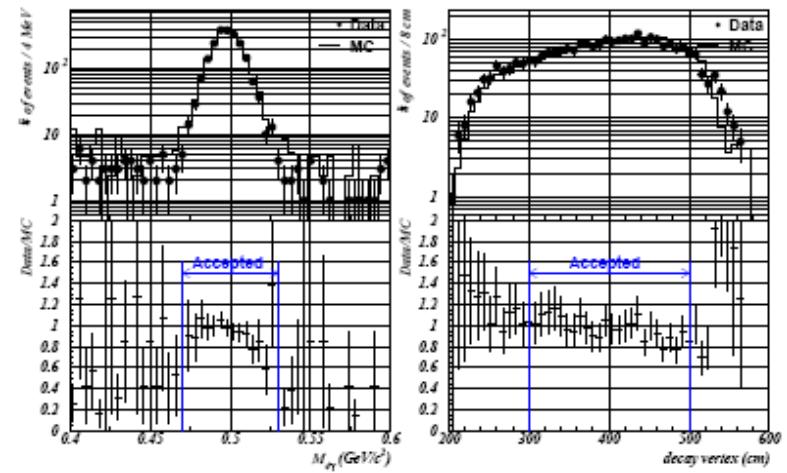

FIG. 4: Distribution of the invariant mass (left) and the decay vertex (right) for the $K_L^0 \rightarrow \pi^0 \pi^0$ decays. In the top plot, the dots show the data and the histogram shows the MC. The bottom plot shows the ratio of the data to the MC.

K10->pi pi nu nubar

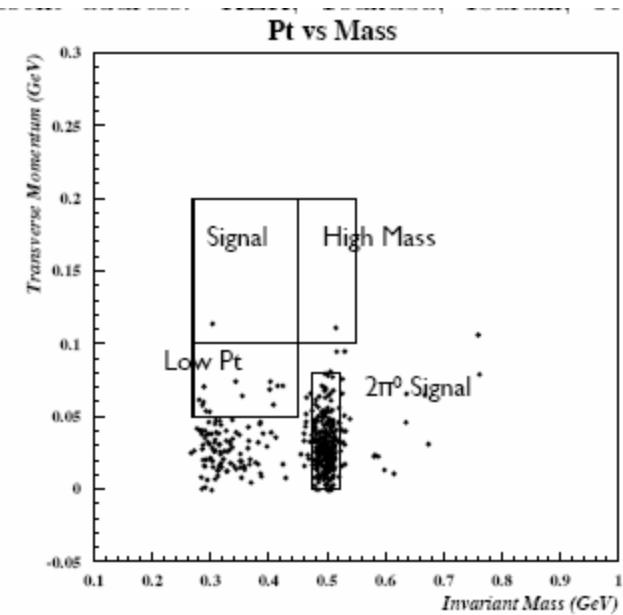

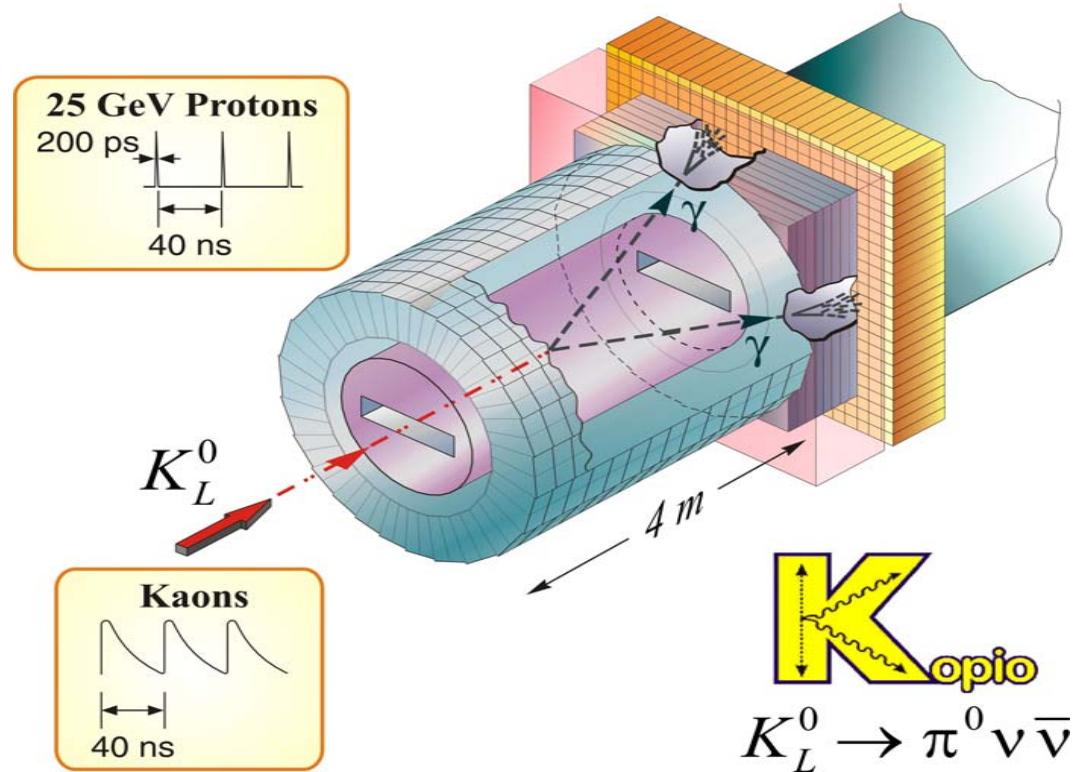

FIG. 4: P_T plotted against mass. The rectangular regions correspond to the regions in Table II.

TABLE II: Prediction of background events in different regions.

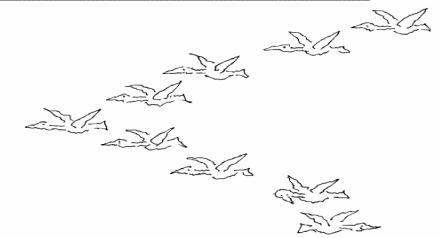

Region	N_{AB}	N_{AB}	$N_{\bar{A}\bar{B}}$	Prediction	Data
Low P_T	380	72	115	21.1 ± 3.3	13
High Mass	46	9	4	0.78 ± 0.48	1
Low Z	5	0	0	0	0
High Z	0	0	6	0	0
Signal	84	18	2	0.43 ± 0.32	1

KOPIO Concepts: Goal >100 events

- Use TOF to work in the K_L^0 c.m. system
- Identify main 2-body background $K_L^0 \rightarrow \pi^0 \pi^0$
- Reconstruct $\pi^0 \rightarrow \gamma\gamma$ decays with pointing calorimeter
- 4π solid angle photon and charged particle vetos

Summary

Rare Decays of μ, π , and K offer unique, clean access to the flavor breaking and CP-violating structure of hypothetical new physics -- access to short distance effects and high mass scales are complementary to collider studies at the LHC.
